Lord Rosebery deserves the thanks of the community for raising his voice against the hideous American method adopted by advertisers of quack nostrums and other purveyors of proprietary articles of fixing boards in conspicuous situations in the midst of sylvan scenery throughout the country. Experience shows that certain pill concoctors have been the worst offenders in this respect, one being English, and the other American. In an interesting letter, however, which we have received from the English agent of the latter manufacturer, we are informed that the practice will be discontinued, and that as soon as the contracts with the farmers on whose land the boards have been fixed, run out, the offending and unsightly structures will be removed. This deference to public opinion affords us undisguised pleasure to chronicle.

Mr. Frederick Treves having resigned the post of Examiner on the Board of the Royal College of Surgeons, England, there will be an election to fill the vacancy on the 14th prox. Candidates, who must be Fellows of the College, should send in their applications to the Secretary before the 6th prox.

Vomiting under Anæsthetics.

The causation of vomiting under anæsthetics, and particularly under chloroform, has not as yet been satisfactorily explained, and it is somewhat vaguely attributed to the toxic effects of the drug employed. Others, again, see in this particular manifestation an indication of idiosyncrasy on the part of the patient, and it may possibly have something to do with the production of this inconvenient and troublesome symptom. At the same time it seems out of place to talk of idiosyncrasy in connection with a symptom which is so general as almost to be universal, the more so as it does not occur with any remarkable uniformity even in the same individual; at any rate, so far as the intensity goes. One observer claims to have noticed that sickness is most marked after anæsthetisation in persons who are peculiarly addicted to sickness on the high seas; but the experience of other trustworthy observers is sufficient to show that this explanation does not always hold good. The most curious thing about the sickness is that it may be well marked at one administration and be conspicuous by its absence at a subsequent anæsthetisation, although, so far as one can judge, the conditions are the same. The sickness is not only troublesome, but is attended by a tangible risk; indeed, the risk of asphyxia consequent on the passage into the larynx of regurgitated food is one of the dangers inherent to the induction of anæsthesia. Anyone who would devise a plan of averting this gastric disturbance would earn the thanks not only of anæsthetists, but of the patients, whose post-anæsthetic comfort is notably interfered with in consequence thereof.

Is the Council of the Royal Society a Clique?

The mere breath of suspicion that a body holding so important a position in the world of science as that of the Council of the Royal Society should be actuated by motives other than those which were eminently straightforward in their dealings with the applicants for the Fellowship, is by no means a pleasant matter to contemplate. Of course, it is easy to understand that at each annual election there must be many cases of disappointment among the candidates who do not happen to have found favour with the Council, and quite possibly, too, some fail to be "selected" whose claims to the distinction are more worthy than those possessed by some of the successful candidates. Presumably, however, this latter contingency is one which only seldom arises. Nevertheless, the proof that it may, and does, occur is to be found in the fact that certain well-known scientific men have failed to secure their election to the Fellowship. Over and above, however, these matters of detail, it has been reported that the Council's deliberations are not entirely free from the influence exerted by the strong representation possessed by one of the older Universities, and that the candidates for election nominated by the representatives in question have always the greatest chance of being successful. It follows, therefore, that if this influence be predominant it could only be employed to the detriment of the claims of other candidates who had not the advantage of its support. If, then, these be the facts, it would appear that the question which gives the title to this paragraph, should be answered in the affirmative. This trade unionism in science is repulsive, and unworthy to be practised by leaders of science.

The Volunteer Commemoration.

Active steps are being taken in Devon to commemorate in the county, in a public and permanent form, the service rendered to the nation by Dr. Bucknill in starting the first Rifle Volunteer Corps (in Exeter), in 1852, and so founding the Volunteer force of the country. Lord Clinton, the Lord Lieutenant of Devon, is to preside at a public meeting to be held at Exeter on the 25th inst., and the movement is being supported by all the leading men of the county. The views which we expressed a short time ago in The Medical Press and Circular, to the effect that some public recognition of Dr. Bucknill's services should be carried out, are now within a measurable distance of being adopted. The medical profession cannot but feel some gratification in the reflection that the conception of, perhaps, the most popular national movement of the present century owed its origin to two of their number. It may be trusted that in the list of Birthday honours, the publication of which may be expected this week, the name of Dr. Bucknill will be included.

Bromethyl as an Anæsthetic.

Bromethyl has for some time past tended to grow in favour with French surgeons, although it must be confessed the reasons advanced for the choice of this new and as yet imperfectly-tried anæsthetic hardly appear to justify the enthusiasm which certain of them profess in respect of its administration. Its suffocating effects when administered alone and undiluted tend to make patients restive, though it is stated that if given in small doses to begin with this effect is not complained of. The more usual plan is to commence the anæsthesia with a preliminary whiff or two of chloroform, in which case it is difficult to see what particular advantage attaches to the substitution of anæsthetic No. 2, for it leaves the risks associated with chloroform narcosis intact, and the sickness which so often follows the inhalation of the latter drug unchanged. So far, the only two deaths which have occurred in Paris from bromethyl comprise two cases in which chloroform was first given, so that it is difficult to state confidently which of the two was the lethal agent. As is usually the case with new drugs, there is a great conflict of opinion and experience as to its merits. While some regard it as an admirable innovation, others as unhesitatingly condemn it. There is a praiseworthy reluctance on the part of professional anæsthetists in this country to try experiments, and this we are fain to encourage even at the risk of overlooking for a time the advantages which may possibly attach to other bodies of what we may call the anæsthetic series.

The Salters' Company has permanently endowed five additional beds in Guy's Hospital at an annual cost of £250.

Medical Missions.

Very little appears to be known of the work done by Medical Missioners in Foreign Countries, India, Africa, &c., and those who are engaged in this field affirm that they, by the nature of their calling as medical men, have opportunities of spreading Christian principles among Mohammedans, Moslems, and Buddists which are denied to the clergy of various denominations. The initiation of the movement is stated to be due to Mr. Wm Welton, a Suffolk surgeon, who was the first to be ordained for the work forty-five years ago, he selecting China, the most unpromising of fields, for his venture. Now there are twenty-five medical missioners belonging to the Church of England alone, besides those sent out by other religious bodies. At a meeting held in London last week the Rev. Dr. Elliott said that he had spent 6½ years at Gaza, a most fanatical Moslem town, where other Christian work was forbidden, and he had been freely allowed to preach Christianity to his patients, whose numbers sometimes reached 180 a day. When he went to Gaza there was not another medical man, with either British or Turkish qualifications, in a population of 28,000. There were only quacks, who beat girls black and blue for hysteria, and gave as a panacea for serious fevers the water with which the name of Allah was washed off a dish on which it had been written. Scientific treatment came as a revelation to the people of all classes, and had a wonderful effect in breaking down prejudice. Another speaker said it was a remarkable fact that even the Jews in Jerusalem braved the excommunication of their rabbis and went to the Christain doctors of the London Jews' Society rather than to the hospitals amply equipped and freely opened by European Hebrews, such as the Rothschilds. Dr. Eustace, of Quetta, said that the works of medical missionaries suffered from insufficient equipment but was otherwise most successful. Medical representatives from the Punjaub and from Kashmir, also addressed the meeting, and much enthusiasm appears to have been exhibited by the success of the movement.

Sir Joseph Lister at Glasgow.

In another column our Scotch Correspondent refers to the address delivered last week to the medical students of Glasgow University by Sir Joseph Lister. The enthusiastic reception which Sir Joseph received on the occasion was nothing more than what was to have been expected. With Sir Joseph's world-wide reputation, and the position to which he has attained in the field of science, it was only natural that the welcome of his *alma mater* should have been distinguished by a sincerity and warmth worthy of one of her most eminent sons. The name of Joseph Lister, as long as the world lasts, will be indissolubly bound up with the advance of surgical science, for probably no man in his time has ever accomplished so much, or, indirectly, contributed so largely to the relief of human suffering and the saving of life. The history of the antiseptic treatment of wounds is the history of a treatment in which the process of evolution is most aptly illustrated; but in all the developmental changes associated with it, Sir Joseph's was the guiding hand which was concerned. We are glad to hear that steps are being taken to collect subscriptions for the purpose of presenting Sir Joseph with his portrait, and, in view of this object, circulars are being issued to all the members of the Glasgow University.

The Savings of a Chinese Leper.

A curious report comes from Philadelphia. A Chinese leper who had been an inmate of the Philadelphia Hospital for several years recently died, and among his effects were discovered bank notes to the amount of £26, which represented his savings. A consultation was held by the authorities for the purpose of deciding the course which should be pursued with respect to the disposal of the notes. Ultimately the notes were forwarded to Washington, and were there cremated, inasmuch as it was not deemed proper to allow them to go into general circulation. Are there no bacteriologists in Philadelphia, or is there no one at Washington who could have pointed out that the notes could have been rendered sterile, and that there is no evidence showing that the infection of leprosy can be conveyed in the manner inferred?

The Dispute at Queen's College, Cork.

The investigation of the late unfortunate differences between the Professors and the President, which we referred to a fortnight since as likely to become the subject of an official inquiry, took place last week. The complaints resolved themselves into a statement that the President was in the habit of assuming authority which he did not possess, ignoring the Professors and the Council, refusing to record or pay any attention to their resolutions and making appointments over their heads. The judgment of the Visitors, delivered by Mr. Justice Holmes, was one of guilty against the President, and he was directed to abstain from such undue assumption of authority in future. At the same time, the complainants were lectured for their inharmonious attitude towards the President, and some of their complaints were dismissed as frivolous.

A Fatality at a London Hospital.

Accidents, of course, are liable to happen, even in the best of regulated institutions, and in the most unexpected manner. An instance of an unfortunate occurrence of the kind has been reported to us in connection with St. Thomas's Hospital. One of the female patients last week, who had been an inmate for some time, in the temporary absence from the ward of the nurse on duty, jumped out of bed, ran to the surgeon's table, snatched up a bottle of nitric acid, and, before anyone could interfere, swallowed the contents of it. Death followed shortly afterwards. In all probability no blame could be attached to anyone for this lamentable occurrence. But we would suggest that it would be more expedient, in view of future contingencies of the kind, that the poisons bottles should be placed under lock and key in all cases in which it is necessary to keep them in the wards. So far as the testing of the urine is concerned it is an open question whether or not it would not be a useful plan to have the samples from each ward sent to a particular laboratory in the hospital, where the necessary examinations could be made, and by this plan do away with the present system of examining the urine in the ward, in which, of course, the usual tests must be kept. Some such arrangement of this description appears to us to be well worth considering.

The Greenwich Workhouse Epidemic.

Owing to the alleged choleraic epidemic of last autumn amongst the inmates of the Greenwich Workhouse, the Board of Guardians instructed their architect, Mr. Dinwiddy, F.S.I., to examine and report upon the old system of drainage, and advise upon its amendment, and he recommended the abolition of the old sewers, and the construction of an entirely new system of drainage and sanitary fittings. The Local Government Board, after due investigation, has now approved the scheme in its entirety, and given the necessary authority for a loan to meet the outlay, and the work will shortly be put in hand by the Guardians.

A Disgrace to the Metropolis.

The columns of a London morning newspaper have been largely occupied during the past week with a discussion on "Human Vivisection in Hospitals." We merely mention the fact to show how sadly deficient in enlightenment the public still must be in respect to the advance of medical science when an editor of a London newspaper will publish articles and letters on the subject, which, in point of sentiment and display of ignorance, would be a disgrace to a contemporary whose editorial offices were situated in Slocum-cum-Podgum.

An inquest was held at the Tewkesbury Rural Hospital touching the death of Harold Rumsey, æt. 16, who died at that institution on the 18th inst. He was suffering from a diseased hip, and an operation being necessary a mixture of chloroform and ether was administered by Dr. Wrangham in the presence of Drs. Turner, Liston, and Devereux. At the close of the operation the patient suddenly ceased to breathe, and, in spite of efforts to restore animation, breathing was never re-established. The quantity of the anæsthetic administered was small. A post-mortem examination revealed the cause of death to be syncope, and a verdict to that effect was returned.

Among the persons summoned at the South-Western Police-court for neglecting to comply with the Vaccination Act was a Socialist who protested in vehement terms against being prosecuted. But Socialists, like other persons, have to obey the laws of the country, and some sound advice upon this subject was conveyed to the defendant by the magistrate while giving the order for vaccination to be performed within fourteen days.

Dr. Edwin Goodall, Pathologist to the West Riding Asylum, author of a recent scientific handbook on the "Microscopical Examination of the Brain," has just been appointed Medical Superintendent of the Joint Counties Asylum, Carmarthen.

Sir Thomas Crawford, K.C.B., late Director General Army Medical Department, has been unanimously elected Chairman of Council of the Irish Medical Schools' and Graduates' Association, for the usual period of three years, vice Dr. Mapother whose term of office has expired.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Sir Joseph Lister in Glasgow.—There was a crowded attendance of students and others present in the Union Hall of Glasgow University on the evening of the 17th inst., when Sir Joseph Lister, Bart., gave an address under the auspices of the Medico-Chirurgical Society. The lecturer said that just a quarter of a century had elapsed since he last addressed the students of the University of Glasgow. Then it was in the dear old college in High Street or in the Royal Infirmary. Now they were met in the fine Union Hall beside the stately pile of the new college. Though so many years had passed, and the outward surroundings were so different, he did not feel like a stranger. Some of his former colleagues were present, and he saw before him many, whose studies it was one of his privileges to guide, who had since risen to positions of extensive usefulness and even high eminence in their noble calling. However little he might have contributed to such results, he could not but feel proud to have been their teacher, and was delighted to meet them again. Sir Joseph then said he would like to say a few words on that all-important subject, the practice of antiseptic surgery. After referring at some length to the use of carbolic acid as an antiseptic, he ventured to commend to them this simple mode of purifying the human skin, so, in the same way, with the hands—that it was not necessary so to purify them that if a portion of the nail were to be cut off and put into a cultivating liquid there would be no chance of microbes developing. Experiments of this kind, he assured his hearers, were made, and often brought antiseptic surgery into contempt. All that was necessary and needful was to purify the hands, the instruments, and all accessories so that they might not be the means of communicating mischief to the wound they were making or dressing by the admission of "gross dirt" and for the prevention of such he advised the use of a 1 in 20 solution of carbolic acid.

Conviction of Asylum Attendants for Assault.—At the Paisley Sheriff Court, on the 17th inst., Elizabeth Reith, Christina Robertson, and Isabella Marshall, recently attendants in the Riccartsbar Asylum, Paisley, were charged with having, on the 1st May, assaulted Jane Murphy or Manson, an inmate, by seizing hold of her, throwing her down on the floor, holding her face downwards, and beating her on the naked body with a piece of wood. Prisoners pleaded guilty, and the first named was sentenced to forty days, and the two latter to thirty days' imprisonment each. It was stated to the Court that the assault was witnessed by another attendant, who reported the matter to the governor. The Asylum Committee of the Parochial Board thereupon gave instructions to place the matter in the hands of the authorities, being determined to put down such conduct.

Outbreak of Small-Pox at Coatbridge.—There is an outbreak of small-pox in Coatbridge at present, and it is causing considerable alarm and anxiety to the sanitary authorities, as daily fresh cases crop up which, on being sent to the hospital, are succeeded by fresh ones. On the 16th inst., two fresh cases were removed to hospital, and on the 17th three new cases were reported from the Whifflet district. The source of the disease has been traced to Glasgow. Strenuous efforts are being made to cope with and stop the further progress of the epidemic, but as yet with no apparent result, as a case has been imported by a joiner from Coatbridge into Airdrie, which is very near Coatbridge. It is feared that, even although this first case has been at once sent out of the district, other sources of infection may be at work.

Glasgow Ear Hospital.—The annual meeting of the subscribers and friends of this hospital was held on the 9th inst. Dr. Barr reported that 1,043 new patients, representing 5,000 consultations, were treated during the year, including 56 cases in the indoor department. Thirty-one operations under anæsthetics were performed. There had been a larger class of students during the winter than usual, 54 names having been enrolled. Dr. Barr awarded the Directors' prizes to Mr. William Stewart Cook, B.Sc., and Mr. John Gillan.

Testimonial to Dr. Miller, St. Rollox.—Dr. Miller, who has been practising medicine in St. Rollox for the last thirty-five years, was presented a few days since with a testimonial, consisting of an illuminated address and a purse of 110 sovereigns. The address stated that a large number of his friends and patients regretted that the state of Dr. Miller's health necessitated his going to New Zealand to seek a more genial climate. Dr. Miller thanked the donors, and said that the beautiful address would be prized as an heirloom.

"UNIQUE CONDITION OF HERNIA."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Cotterell's suggestion in your last issue with regard to the possible nature of the sacless hernia described in my case ("Operating Theatres" in Medical Press, May 9th), is a very natural one. The same idea arose in my own mind at the time, that the muscular viscus might be bladder, but I drew the hernia out from the wound to a sufficient extent to ascertain that it was a tube, and that it could be traced outwards and backwards in the direction of the iliac fossa. This should have been stated in the report. Had I felt any doubt as to its identity with intestine I should have had a catheter introduced into the bladder to decide the point.

I am, Sir, yours, &c.,
William Anderson.

Harley Street, London.
May 19th, 1894.

COUNTER-PRESCRIBING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Sir W. Benjamin Richardson must have received a rude shock to his recently-propounded scheme if the case reported in the newspapers last week was brought to his notice. Although the practice of prescribing, and even visiting the patients of medical men, by chemists is so widespread and universal, yet I fancy that the magnitude of the evil is but dimly recognised. It is only in those rare instances where a death occurs that the prescribing part of the chemist's business is brought into prominence, and he becomes the object of a mild censure from a coroner's jury. In the extraordinary case which came before Mr. Coroner Hicks last week, one of these pretenders had actually attended a consumptive patient for four years, during the first twelve months of which period he had not even qualified as a chemist! For his unqualified services he charged at the rate of half a guinea a visit, an amount in excess of what many a highly-qualified University graduate would have ventured to ask. His knowledge of disease and its treatment had been picked up, by his own admission, under an unqualified chemist, who appears to have run a medical botanic depôt for a number of years.

Now, Sir, I would submit that the safety of the public, no less than the interests of the medical profession, demands the instant suppression of that cruel social parasite, the prescribing chemist, and not his registration, as Sir B. W. Richardson suggests. The medical man, in the event of a proved malpraxis, is subject to heavy penalties. Surely the law of the land should be so framed that the malpraxis of an unqualified chemist should be met with vastly greater punishment. Let it be remembered that every act of his in the direction of prescribing or of treatment necessarily constitutes of itself, and by its very nature, a deed of malpraxis.

An enormous amount of venereal disease is treated, or mal-treated, by chemists, as well as diseases of the skin, of the eye and for that matter, of every branch of medical and surgical practice. Nothing, indeed, is sacred from his greed and his pretentious assumptions. Every single act of the kind implies a distinct robbery of medical men, who have spent much time and money in acquiring an adequate knowledge of a profession, which, alas, too often affords them in return nothing more than the bare possibilities of a struggling and precarious existence.

In conclusion, I would ask what the Apothecaries Society, assuming that the newspaper reports of the case above alluded to are correct, was about when it allowed the training of a botanic depôt to qualify for its diploma?

Trusting you will open your columns to a correspondence on this subject, which is one of the utmost importance to the profession at large,

I am, Sir, yours, &c.,
Indignans.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—A correct diagnosis is at the basis of all rational treatment, medical or otherwise. The first step, before prescribing for a patient, is to ascertain what is the matter with him. Now this is precisely what the retail chemist cannot be expected to undertake. Given an exact diagnosis, an experienced and intelligent chemist might very possibly be able to indicate an appropriate remedy—if one there be—but his education does not render him more apt at identifying diseases than "the man in the street." To talk of legitimising counter-prescribing is, therefore, preposterous unless to the usual pharmaceutical course be added a course of clinical medicine.

To tinker symptoms—which is all even the most intelligent chemist can do—is to risk treating diphtheria as simple sore throat, typhoid fever as summer diarrhœa, and pyosalpinx as dysmenorrhœa, &c.

To seek to render it penal, on the other hand, is impracticable because public opinion would run counter to any such proposal. All we can ever hope for is that actual damage, due to presumptuous ignorance, shall be made to create a civil liability.

I am, Sir, yours, &c.,
Alfred S. Gubb,
M.D. (Paris).

"THE CLERICAL LUNACY CASE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As you have recently published some letters from correspondents on "What Constitutes Unsoundness of Mind?" and you last week made some very potent remarks on the "Clerical Lunacy Case," the ridiculous state of the law on insanity is again thereby demonstrated. I ask, therefore, to be allowed, in illustration of this, to mention a trumpery case instituted in a County Court. The County Court Judge allowed an appeal, and further it eventually spins itself into a question of such legal magnitude that it was tried in the House of Lords, the ex-Law Lords and the Chancellor giving their judgment. But let us suppose the legal machinery was so badly organised here that it was allowable for the whole of these proceedings to be rescinded by a jury without any legal training whatever. What respect could the ordinary run of lawyers have for their Law Courts? and how, therefore, is it possible medical men can respect them? A case being certified by two medical men as insanity, its removal to an asylum, a kind of court of appeal consisting of the Visiting Commissioners, &c., reviewing the proceedings, and, finally, the highest authority on insanity, and, as in this case, Drs. Bailey, Savage, and Maudsley, giving judgment, after which these proceedings are *liable* to be rescinded by twelve gentlemen who may have had no training whatever on the subject they are called upon to adjudicate. To say the least, such proceedings are, as lawyers call it, highly "vexatious," and to say the most, they are a source of great public danger, and notwithstanding the late Lord Westbury's celebrated dictum to the effect that any ordinary man of the world is as good a judge of insanity as anybody. This dictum appears to me to be refuted by experience, because in a text-book I prize, a case is related where an insane person was submitted to the judgment of a jury, and the person was about to sign his discharge, they having concluded he was not insane, and the escape was so hair-breathd, and the public risks so appalling, that it almost reminds one, as in funeral obsequies, of hearing a rapping in the coffin ere the earth is closed in. I say in the case I recite the person about to be discharged signed himself "Christ"!

I am, Sir, yours, &c.,
Clement H. Sers.

Queen's Road, Peckham, S.E.
May 17th, 1894.

THE TREATMENT OF FRACTURE OF THE PATELLA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Is the use of "Malgaigne's hooks" being revived in the treatment of fracture of the patella? The answer to this question would appear to be in the affirmative, judging from the remark of a London hospital surgeon. He had been summoned by a practitioner for the purpose of suturing a fracture of the patella, but on his arrival proceeded to bring the fragments together with "Malgaigne's hooks," and in reply to the practitioner stated that his colleagues at the hospital to which he was attached had adopted this method of treatment in preference to the operation of suturing, and that he himself had found it very useful. It must be news to a good many operating surgeons to learn that there is a hospital in London at which the treatment of fractured patellæ has reverted to the old, and what has been described as "barbarous," use of "Malgaigne's hooks," despite the improvements which have been introduced in the mode of their application. Probably the question to which most surgeons would like to have an answer would be, Why has this reversion to an old type of treatment taken place? For obviously, so far as the results are concerned, the operation of suturing far surpasses every other method of treatment. Even in the detail of the economy of time effected by this procedure, the patient gains very extensively. After the operation in these cases, the rule is for the splint to be removed at the end of fourteen days, and for another fortnight the patient is allowed to kick his leg about in bed. At the end of six weeks the patient is able to walk out of the hospital with, in all probability, bony union at the seat of fracture. Plainly, no results with any other form of treatment of fracture of the patella can compare with these! It goes, however, without saying, that strict antisepticism is imperatively called for in the operation of suturing the patella, and presumably no surgeon would undertake the operation unless he were confident of his capacity to act in exact accordance with the principles of Listerism.

I am, Sir, yours, &c.,
Antisepsis.

◆

"HOSPITAL ABUSE AND THE REMEDY."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—That the remedy for hospital abuse is to be found in the endorsement of all hospital tickets by private practitioners as "M.D." suggested in *The Echo*, and as referred to in your "Notes on Current Topics" in this day's issue of The Medical Press and Circular, is strongly, and further, plainly indicated in the "Bye-laws, and Regulations of the Royal College of Physicians of London," a copy of which I now quote from. Bye-law No. 175 reads thus "No Fellow, Member, or Licentiate of the College shall officiously, or under colour of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified Medical Practitioner." Now, I have it on the authority of a hospital physician that a good half of those frequenting hospital out-patient departments, are there whilst in this position with reference to their medical attendant, and without any request from him to the hospital physician to give an opinion or take over the case.

The argument that these gentlemen are not bound to inquire into the matter, but must take all who come with tickets of admission, "will not hold water." It follows therefore, that there are at this moment hospital physicians by the score who are continually violating a Bye-law of the College relating to Fellows, Members and Licentiates of the same; and are consequently in danger of being reprimanded, or fined £10, or declared no longer Fellows, Members, or Licentiates of the same, and thus of forfeiting all the rights and privileges they enjoy by having their names "expunged from the List of Fellows, or Members, or Licentiates as the case may be."

All this law-breaking, with its consequent dangers, might be entirely avoided by taking private practitioners into their confidence and requesting them to send to hospital "by endorsement" such cases as are suitable for treatment there.

The gain to hospital physicians and surgeons would be greater by far than to private practitioners, whilst "hospital deficits" would become things of the past.

I am, Sir, yours, &c.,
C. R. Illingworth, M.D., D.P.H.

May 16th, 1894.

DIFFERENTIATION OF TYPHOID AND TYPHO-MALARIAL FEVER.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—With your permission, I draw the attention of your readers to the following differences between typhoid and typho-malarial fever drawn up by Dr. F. L. Sim, of Memphis, Tennessee. Dr. Sim is Professor of the Practice of Medicine, and Dean of the Faculty of Medicine of the Memphis Medical College.

The statement copied occurs in a paper read before the Tri-State Medical Association of Mississippi, Arkansas, and Tennessee. He writes:—

1. "The fever we have in this part of the country every autumn and called typho-malarial, is not an acute infectious disease; typhoid fever is.
2. "Typho-malarial is probably due to pathological changes, the result of long continued exposure to malarial influences; or theoretically, to one or more of the six or eight parasites found in the blood of patients suffering from malarial fevers—to some of these quinine is said to be non-toxic. Typhoid is due to a specific poison.
3. "The incubation and duration of typho-malarial are much less fixed than that in typhoid.
4. "The temperature range of typho-malarial is less uniform and regular than that of typhoid.
5. "Diarrhœa is often wanting in typho-malarial, and rarely absent after the first week in typhoid.
6. "The typho-malarial tongue never evidences the gravity of the disease that the typhoid tongue does.
7. "I have never seen sordes on the teeth, gums, lips, and in the roof of the mouth, in typho-malarial; I have frequently in typhoid.

8. "I have never discovered the typhoid eruption on the persons of typho-malarial patients. It occurs in eighty-eight per cent. of typhoid patients.

9. "Bronchial and pulmonary symptoms are rare in typho-malarial, common in typhoid.

10. "The nervous symptoms in typho-malarial are absolutely wanting in comparison to their constancy and gravity in typhoid.

11. "The gut pathology of typhoid fever, as discoverable by the symptoms, exists in a much smaller percentage of cases in typho-malarial than in typhoid.

12. "By the intestinal dejecta, typhoid fever is disseminated; there is no evidence that this is true of the dejecta of typho-malarial."

The Mississippi Valley gives unrivalled opportunities for the study of typhoid and typho-malarial fever, and no man has better means of comparing them than the Editor of your contemporary, the *Memphis Medical Monthly*, Dr. F. L. Sim.

I am, Sir, yours, &c.,
George Foy.

WOOD WOOL MATTRESSES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In this age of antiseptics we cannot be too clean, and it has always occurred to me that hair mattresses were not free from suspicion as sources of contagion; we know that they are largely used in our hospitals, and we have no reason to believe that they are new when bought as the stuffing may have been in use many times before, though the outside may appear spotlessly clean.

Hair mattresses are expensive, less so, probably than the old and now generally condemned feather bed, upon which so many of our ancestors breathed their last, but nevertheless, too costly to be discarded for slight stains or even slight saturation with discharges; now if a comfortable mattress could be got which could be relied on as containing antiseptic contents and at the same time comparatively much cheaper than the generally used and doubtful hair-stuffed article, I consider a great thing for our poorer patients would have been accomplished, and this ideal mattress is to be found in one stuffed with wood wool. The wood wool mattresses are cheap, they are clean, and they are very comfortable when placed on the ordinary hospital spring bed, and as regards their antiseptic contents they are above suspicion. Every medical man of experience in this country knows what wretched bedding is provided for paupers in many of the unions, and that the county asylums are not without reproach in in this respect. In doing away with straw beds and providing themselves with wood wool, many of the unions have done well, and I trust that more institutions will shortly provide themselves with this cheap and cleanly article, and thus remove from our wards these hair-stuffed foci of disease.

I am, Sir, yours, &c.,
R. R. Leeper, F.R.C.S.I.

Rathdrum.
May 2nd, 1894.

Literature.

PIERSOL'S NORMAL HISTOLOGY. (a)

There is a freshness of style and treatment to be found in this excellent text-book that will cause it to become a favourite alike with student and practitioner. The wood cuts are numerous, original, and very clearly printed. In places where differences of opinion exist as to the function or constitution of a structure the author gives the views held by the different schools and then modestly advances his own. In a book of this kind it is not always easy to steer clear of the Scylla of brevity on the one hand and the Charybdis of too great detail on the other. In the present case, however, the author appears to us to have struck the happy mean as nearly as possible. The development of the tissues has been touched on sufficiently to awaken an intelligent interest in the appearances of the fully developed structure. We can confidently recommend this as a really meritorious text-book.

LEGG ON THE URINE (a).

In this, the seventh edition of Dr. Legg's "Guide to the Examination of the Urine," the wide subject is treated in the comparatively limited compass of 136 small pages. The result is that in many instances clinical usefulness has been sacrificed to condensation. Many subjects interesting to the practitioner are entirely omitted. The three subjects of the greatest importance to the clinician in connection with the urine are "albumen," "urea," and "sugar." The sections devoted to their consideration by Dr. Legg are certainly too short, and some of the observations are misleading. In connection with albumen testing by boiling it, &c., it should have been pointed out that if purposely or accidentally one or two drops of nitric acid be added to urine containing albumen previous to boiling, no precipitate at all results, the albumen having been converted into a form of nitrate of albumen which is not coagulable by heat. A frequent source of error in urine testing, the precipitation of urea by nitric acid, should have been noted and the distinctions between this precipitate and albumen emphasised. "Copaiba taken internally causes a precipitate to appear in the urine with nitric acid in the cold, and so imitates the coagulation of albumen." It should have been added that this precipitate disappears on heating. The statement that "the presence of casts in the urine is a sure sign of disease in the kidney" is misleading, as casts may be found in the urine when certain substances passing through the kidney give rise simply to irritation, as is often found in jaundice, after the ingestion of phosphorus, cantharides, and certain other irritating diuretics. For the estimation of urea two processes are described, viz., Southall's, and Russell and West's. Gerrard's process is much more accurate and convenient than either. In a book intended for the bed-side some notice should have been taken of "functional or physiological albuminuria." Some of the illustrations from photographs are not very well defined, the others, the old ones, are good. While we consider the descriptions of certain of the processes too bald, and while many clinically important subjects are omitted, the book, so far as it goes, constitutes a reliable bed-side guide to urinary analysis and the symptomatology of urine.

DONKIN'S DISEASES OF CHILDHOOD (b).

This clinical work, based on the writer's twenty years' experience acquired at hospitals for children, contains much valuable information, put before us in a clear and concise manner.

As the author states in his preface, the reader's general knowledge of the diseases discussed is assumed, and the points more particularly pertaining to childhood emphasised, but in some instances, at all events, throughout the work we think that this assumption has been carried too far, and in the description of the treatment of some diseases almost peculiar to children, completeness has been most unfortunately sacrificed to brevity.

Some of the sections, however, are exceptionally good, and in that on Febrile Diseases, the articles on Diphtheria and Rubella are well written, particular attention being rightly drawn in cases of the latter to the great difficulty of diagnosis. The main conclusions of an Investigation of the Clinical Society of London on the periods of incubation and contagiousness in these Febrile Diseases is contained in an appendix to this section, and is likely to prove useful to the practitioner. The book we may add is a practical one not burdened with numbers of quotations from other writers, and not hampered by minute details of individual cases. The author appears to have studied his own cases critically and well, he gives the records of his own observations, and does not hesitate to express his opinion very plainly on several popular methods of treatment.

(a) "A Text-book of Normal Histology, including an account of the Development of the Tissues and of the Organs." By George A. Piersol, M.D., Professor of Anatomy in the University of Pennsylvania, Philadelphia 429 pp. London: Baillière, Tindall, & Cox. 1894.

(a) "A Guide to the Examination of the Urine." By J. Wickham Legg, F.R.C.P. Seventh Edition, revised and enlarged by H. Lewis Jones, M.A., M.D., M.R.C.P. London: H. K. Lewis. 1893. Foolscap 8vo. pp. 136. 3s. 6d.

(b) "The Diseases of Childhood (Medical)." By H. Bryan Donkin, M.D. Oxon, F.R.C.P., Physician to the Westminster Hospital and East London Hospital for Children at Shadwell, &c. London: Charles Griffin and Co., Limited.

He may be congratulated on having put the Diseases of Childhood before his readers in an interesting and instructive manner.

AIDS TO OTOLOGY. (*a*)

The general practitioner who cannot manage sufficient time to read a large treatise on diseases of the ear, and for senior students going up for examination, this little book—one of the best of this excellent series—will be very useful. Of necessity the statements are very brief, but they are clear and practical; and fully ninety-nine per cent. of the cases that crop up to the general practitioner, or are submitted to the candidate for examination on this subject, find a place in Dr. Stewart's book which is a veritable aid to otology.

A DICTIONARY OF APPLIED CHEMISTRY. (*b*)

Everything must come to an end in time, and Prof. Thorpe concludes his important work by a third ponderous volume of 1,085 pages. It takes us from "Oak Bark" to "Zymurgy." We think we can hear many of our readers exclaiming what is zymurgy? Well our readers had better look in the dictionary, *i.e.*, Thorpe's, not Johnson's. To the experimentalist a science dictionary is always an unsatisfactory work. The necessary, scanty, and sketchy information which must necessarily be found therein gives but little satisfaction to the experimentalist, but the writer after some two years experience of the previous volume of this work is compelled against a mental predilection, to bear testimony to the wonderful store of information which have been so judiciously arranged in Thorpe's work. It contains many important monographs upon subjects from special contributors. However good these may be as essays upon important points, they could not constitute much to the utility of such a work, were it not that the constructor and editor is a thoroughly practical man, who grasps the requirements of his readers. Prof. Thorpe has done himself justice in this respect, and laid the scientific chemist under no small amount of obligation. *Apropos* of contributors, as a sign of the march of the scientific training, a lady contributor, Mrs. A. H. Green, has written an elaborate article upon tea. This lady has evidently gone far beyond the physiology of afternoon teas, and a valuable monograph dealing with botany, cultivation, preparation, chemistry, and analysis of tea is the result.

Some of the most important articles are upon essential oils, fixed oils, vegeto-alkaloids, opium. The article upon opium sums up as follows:—The physiological action of opium when smoked is clearly quite different from what it is when taken into the stomach. The writer also notes that the opium, containing least morphia is most prized for smoking. It would seem that, notwithstanding the serious views held of the effects of opium smoking by both the Chinese Government, and amongst Europeans, the habit is not more injurious than the use of other stimulants in Europe. Opium in the East performs the same functions that alcohol does in the West, and as far as can be ascertained, with about the same good and evil effects.

The article upon theormostats will no doubt be consulted with considerable interest by the bacteriologist and the scientist generally. The completion of this important work reflects great credit upon the publishers as well as the editor. Good paper, good type, and abundant care in the revision of the work are plainly evident, and the care expended in illustration where necessary is well shown in the article last mentioned.

(*a*) "Aids to Otology." Second Edition of Epitome of Ear Diseases. By W. R. H. Stewart, F.R.C.S.E., Aural Surgeon to the Great Northern Central Hospital, Surgeon to the London Throat Hospital, late Surgeon to the Throat Hospital, Golden Square, and Surgeon in-Charge of the Ear and Throat Department, North-West London Hospital. London: Bailliere, Tindall, & Cox, King William Street, Strand. Edinburgh: Livingstone. Dublin: Fannin & Co. Glasgow: Stenhouse.

(*b*) "A Dictionary of Applied Chemistry." By T. E. Thorpe, B.Sc. assisted by eminent contributors; in 3 vols. London: Longmans Green, and Co. 1893.

Obituary.

INSPECTOR-GENERAL DR. H. A. BRUCE.

By the death, a few days since, of Dr. H. A. Bruce, Principal Inspector-General H.M. Forces, and late of the Bengal Medical Service, one of the oldest officers of that service has passed away at the ripe age of 86. Deceased studied at the University of St. Andrews during the two sessions 1823 and 1824, and in 1825 he migrated to Edinburgh, taking the diploma of the Royal College of Surgeons in 1828, and the M.D. Edin. in 1829. In 1830 he was appointed to the Bengal Medical Service, and rose through all the administrative grades of that service to its head. Dr. Bruce saw much active service in the earlier part of his career in India. At the outbreak of the Mutiny in 1857, he held a staff appointment at Cawnpore, but his health had been failing, and just before the outbreak he was sent to England on medical certificate. It is believed that he was the last officer who left the station, and so unconsciously he escaped the massacre; for with two exceptions not a man, woman, or child of the whole garrison escaped the murderous hands of the Nana. On his return from England in renewed health, after twenty months' absence, he was promoted to the administrative branch of the service as D.T. Inspector-General of Hospitals at Ambala, in the following year as Inspector-General of the Upper Provinces, and in 1864 he was raised to the rank of head of the service as Principal Inspector-General. In 1866 he returned to England, when he retired, after thirty-five years' service, to a quiet spot on the Firth of Forth, where he died 28 years after.

Medical News and Pass Lists.

A Royal Present.

With a perspicacity which characterises the doings of that enterprising firm, Messrs. Burroughs, Wellcome and Co., the International Congress which recently took place at Rome was made the opportunity to present to His Majesty the King of Italy a portable field medicine chest, fitted complete throughout with tabloids, and in every respect similar to those supplied by the firm for the great expeditions. The gift has, we understand, since been acknowledged by His Majesty in a very cordial manner, in which he expresses his appreciation of the chest "designed with intelligent care and attention."

A Medical Man Fined for Contempt of Court.

The inquest on the body of a man named Cooper, a shoemaker, who was shot by a man named Winters, who afterwards committed suicide, in Goldsmiths-row, Hackney-road, was considerably delayed by the action of Dr. O'Regan, who declined to hand over the revolver with which the crime was committed. The inquiry had to be adjourned, and Dr. Regan then produced the weapon. He asked for his fee as a medical witness, but instead was fined £1 by Mr. A. Hodgkinson, the deputy coroner, for his conduct in the matter. The doctor said that he should appeal against the coroner's decision, and has done so, with the result that he has been informed by the Treasury Commissioners that they decline to remit the fine.

Royal College of Surgeons of England.

The following candidates for the Fellowship passed the first professional examination in Anatomy and Physiology at a meeting of the Board of Examiners on Thursday, 17th inst.:—Messrs. Wm. M. Stevens, M.R.C.S. Eng., L.R.C.P. Lond., and Claude C. Chidell, M.R.C.S. Eng., L.R.C.P. Lond, University Coll., London; William E. Plummer, Guy's; John A. Spear and John P. Maxwell, St. Bartholomew's; Arthur H. Evans, Westminster Hospital; and John J. Waddelow, M.R.C.S. Eng., L.R.C.P. Lond., King's Coll., London. Nine others were referred back to their professional studies for six months.—The following candidates passed on Friday, the 18th inst.:—Messrs. Albert E. Walter, Middlesex Hospital; John D. Russell, University Coll., London; Arthur G. Butler, Guy's; and Harold M. Cooper, St. George's. Twelve others were referred back to their professional studies for six months.

The Conversazione at the Medical Society, London.

The President and Council of the Medical Society were "At Home" on Monday evening last, and a large number of the Fellows and their friends foregathered in response to the invitations to the one hundred and twenty-first *conversazione*. The proceedings commenced by the delivery of the oration by Dr. William Ord, F.R.C.P., the subject being "A Doctor's Holiday." After the usual vote of thanks, the President's reception took place, and then the scientific aspect of the meeting soon began to assume a "smoky" appearance, the result, not particularly of any special meteorological condition, but rather the effect of the company present endeavouring to indulge in a little recreation. At 10 p.m. Mr. Robert Ganthony gave a "variety entertainment," and a selection by the Bijou Orchestra in the Hall aroused the scientific echoes of the building.

Health of Ireland for the Past Quarter.

According to the Registrar-General's return for the quarter ending Saturday, March 31, in the Dublin Registration District there were registered during the thirteen weeks 2,542 births, being equal to an annual rate of 29·1 in every 1,000 of the population. The rates were—for London during the same period, 31·3 in every 1,000; in Glasgow, 33·0; and in Edinburgh, 25·9 in every 1,000. Deaths: The deaths registered in the Dublin District afforded an annual ratio of 31·5 in every 1,000 of the population. The average rate in the first quarter of the last ten years was 32·2 per 1,000 persons; thus the rate (31·5) for last quarter was 0·7 under the average for the March quarter. The rate for London during the quarter was 21·1 in every 1,000, in Glasgow 21·6, and in Edinburgh 18·4. The deaths from zymotics in the Dublin District were 382, being 6 over preceding quarter, 90 in excess of the average for the first quarter of the ten years, 1884-93, and 127 over the number for the first quarter of last year. The annual rate per 1,000 of the population, represented by the deaths from these diseases during last quarter, is 4·4, being 1·0 over the average rate for the corresponding quarter of the last ten years, and 1·5 over the rate for the first quarter of 1893. Nearly one-fourth of the total mortality from zymotic diseases was caused by whooping-cough, the deaths from which amount to 93, or 35 over average. The deaths from influenza and its complications were almost as numerous as those from whooping-cough, amounting, as they did, to 87, against an average of 27. It will be observed that the increase in the deaths from these two causes, whooping-cough and influenza, more than covers the excess in the general mortality from zymotic diseases as compared with the average for the March quarter. Deaths from enteric fell last quarter to 32, which number is 43 under that for the corresponding quarter of last year, and 9 under the average for the first quarter of the ten years, 1884-93. The hospital returns also show a large decline in this disease, the total number of admissions for the quarter being 115, or 156 under the admissions for the preceding three months, and showing a decrease of 59 or 34 per cent. as compared with the number for the first quarter of last year. The deaths from diseases of the respiratory system (exclusive of phthisis) are 677, or 25 per cent of the deaths from all causes. The provincial death-rate during last quarter in the Dublin District and fifteen of the principal urban sanitary districts of Ireland was 29·0 per 1,000 persons. Small-pox: No deaths from small-pox were registered fn any of the fifteen districts. Measles caused an annual rate of 2·4 per 1,000 in Belfast, where 79 deaths from the disease were registered during the preceding quarter. Typhus: There were only 8 deaths from typhus recorded, being 10 under last year. Whooping-cough, which has been for some time prevalent in Belfast, caused 87 deaths in that city during last quarter, which number is equal to an annual rate of 1·3 per 1,000 of the living at all ages.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 30, Bombay 37, Madras 35, Paris 22, Brussels 19, Amsterdam 20, Rotterdam 26, The Hague 15, Copenhagen 21, Stockholm 18, Christiania 27, St. Petersburg 28, Moscow 38, Berlin 17, Hamburg 17, Dresden —, Breslau 24, Munich 25, Vienna 24, Prague 32, Buda-Pesth 32, Trieste 29, Rome 20, Turin 23, Venice 18, Cairo 48, Alexandria 43, New York 22, Brooklyn 18, Philadelphia 19, New Orleans 20.

Edinburgh University Passes.

The following is the list of the candidates who have passed the First and Second Professional Examinations last month, along with the names of two candidates who have been awarded the Thomson Bursary and the Vans Dunlop Scholarship:—

Old Ordinance—*First Professional Examination.*—William Anderson, F. J. H. Bateman (B.A.), J. B. Boyd, C. W. Breeks, A. J. W. Buchanan, Joseph Cæsar, C. J. Caddick, Selwyn Champion, M. N. Chadhuri, E. V. Collins, Matthew Corry, T. M. Coutinho, G. L. K. Finlay, J. V. Fox, W. C. H. Forster, W. H. Goldie, James Grieve, S. J. Grinsell, W. J. H Hislop, J. T. Hurst, A. H. James, F. F. Kerr, John Mackenzie, Marcus Mackenzie, M. W. Manuk, B. N. Mullen, E. J. Nichols, D. J. C. Oliver, F. W. Rigby, N. H. Ross, D. C. Sethna, John Stevenson, G. R. Twomey, Mohamed Varis, R. H. Walter, J. O. Williams, and W. E. Williams.

New Ordinances.—D. V. M. Adams, A. J. T. Allan, V. G. Alexander, J. R. Anderson, E. P. Bauman, William Bell, H. L. S. D. Belasco, Stanley Branch, William Burns, (M.A.), A. E. Burroughs, David Clow, R. V. Cowey, Robert Crawford, Robert Cumming, L. W. Davies, R. J. Dick, W. H. Dickinson, J. E. Dods, C. L. Dunn, W. S. Eaton, Duncan Forbes, A. Fordyce, J. S. Fraser, A. T. Gailleton, Alexander Goodall, J. H. Gordon, William Gorrie, J. T. P. Heatley, Rowland Hill, Patrick Kinmont, F. O. Lasbrey, E. W. Lewis, J. S. Low, W. C. M'Kechnie, R. W. Mackenna, W. W. Maxwell, James Miller, J. D. S. Millo, L. H. B. Mills, W. J. Nutter, F. M. Parry, H. R. Phillips, Robert Pugh, J. A. Raeburn, J. M. Reid, Thomas Rogerson, R. F. M. Scott (with distinction), W. M. Smith, Edgar Somerville, G. H. Stewart, William Tarr, Henry Taylor, W. B. Thain, A. H. Thompson, G. E. Twigge-Molecey, W. E. Wallis, W. C. Wilson, Alic Wood, A. G. Worrall, and G. J. Young.

Second Professional Examination.—James Allison, H. H. Balfour, James Bannerman, N. D. Bardswell, W. J. Bell, G. J. Blackmore, J. B. Blaikie, A. S. Brass, H. S. Brockway, Daniel Brough, Scott Carmichael, H. C. Colman, A. J. Copplestone, W. J. C. Coulthard, John Crawford, R. W. Cunningham, James Davidson, J. M. Dawson, M. V. Dee, D. F. Dewar, Arthur Dickson, A. F. Evans, David Evans, William Evans, F. W. B. Fitchett A. W. Fletcher, J. A. Forrest, W. C. H. Forster, G. B. French (with distinction); Frederick Gardiner, J. W. Geddes, W. E. Gibbons, F. M. Gibson (B.Sc.), John Gilchrist, J. D. Gilruth (M.A.), Lewis Grant (M.A.), D. J. Graham, W. T. Grant, James Gray (M.A.), Rhodes Haygarth, C. M. Hector, George Henderson, G. P. Henderson, J. H. Henderson (B.A.), J. J. Hewison (M.A.), J. T. Hewetson, A. L. Husband, F. R. Jones, George King, James Kirk, J. H. Lamb, H. A. Leebody, G. R. Leighton, R. M. Leith (with distinction), W. J. Lewis, William Lillie, G. R. Livingston, J. R. Lord, A. M. Love, W. L. Lyall, Alexander MacCarthy-Morrogh, John M'Donald, W. M. Macdonald, W. C. W. M'Dowell, T. H. Macfie, John Maciver, D. M. Mackay, Charles MacLaurin, John Macmillan, J. L. Marjoribanks W. R. Mander, J. S. Martin, James Massey, G. H. Masson, Joseph Mason, R. A. Milne, J. R. Muir, J. G. P. Murray (with distinction), A. G. Naylor, S. D. Ogilvy, T. T. Ormerod, Richard Owen, A. D. Peill, W. J. Pentold, W. H. Price, G. L. Procter, R. B. Purves, J. K. Raymond, E. S. Reid, E. G. Richards, Hugh Richardson, Thomas Roberts, R. S. Rodger, R. L. Roe, L. C. Saldanha, A. T. Sampson, E. W. K. Scott, J. G. C. Scott, T. M. Scott, T. B. M. Sherwen, C. M. Simpson, E. M. Skeete (B.A.), J. E. W. Somerville, James Stenhouse, Alexander Steven, J. B. Stewart, John Stoddart, J. C. Stuart (with distinction), A. C. Sturrock, M.A. (with distinction), D. C. Sutton, H. F. L. Taylor, F. S. C. Thompson, W. H. Thomson, David Waterston, James Watt (B.A.), H. G. Waugh, G. A. Welsh, L. A. Williams, G. H. Wilson, and A. D. Yule (with distinction).

The following candidates have passed in Anatomy and Physiology:—

John Ballantyne, Edwin Bramwell, John Bruce, W. J. Buchanan, W. H. Carse, J. H. Dixon, H. O. Dougall, A. W. Easmon, A. M. Fleming, Thomas Gibson, W. G. C. Geekie, William Hewison, W. H. Hill, J. F. Lindsay, A. P. Low, Stuart M'Donald, A. D. Macpherson (M.A.), M. W. Manuk, F. H. Merry, William Mowat, J. S. Norwell (B.Sc.), A. L. Owen, A. J. Park, W. T. Ritchie, W. H. Robb, David Rodger, J. T. Shirlaw, F. O. de Souza, G. E. Stewart, Robert Thoruton, Andrew Wallace, A. E. White, and G. F. Whyte.

The Thomson Bursary, in the subjects of the preliminary examination, has been awarded to Mr. James Masson.

Navy Medical Service.

The undermentioned candidates, who competed on the 7th inst. and following days at Examination Hall, Victoria Embankment, for appointment as Surgeon in the Royal Navy, have been granted commissions:—

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

RE "THE OLDEST MEDICAL MAN IN EUROPE."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With reference to your annotation under the above heading I beg to say that in the list of members of the Royal College of Surgeons, England, the name of W. Salmon, Penllyne Court, Glamorgan, will be found, diploma bearing date 1809, *vide* Calendar of College, issued under July 7th, 1893. As we may safely presume that Mr. Salmon was at least 20 years of age when admitted, it is to be assumed that he is now set. at in or about 105. Therefore Dr. De Boissy, being aged only 101 years, must now haul down his colours and admit that Britannia rules not only the waves but the ages as well.

I am, Sir, yours, &c.,
T. B. C.

London, May 18th, 1894.

Q. R.—There is nothing for it but to pay! *Dura lex sed lex.*

TUMOURS REMOVED BY LETTERS PATENT!

BY the legal revocation of a so-called patent, last week, one less of those wonderful nostrums, which heal everything and cure everybody has ceased to trouble "the weary who are at rest." It was in the Chancery Division of the High Court of Justice, before Mr. Justice Kekewich, that the Pharmaceutical Society of Great Britain presented a petition for the revocation of a patent which had been taken out by one David Wilkinson, of Ripley, Derbyshire, for the removal of tumours, abscesses, and other useless excrescences. His Lordship made an order in accordance with the prayer of the petition, and the defendant retired.

DR. R. P.—There is doubtless a "medical aspect" to the London Streets and Buildings Bill, but we fail to see that this is any justification for inflicting upon us four columns of prose directed thereto. Everyone recognises the value of air and light, and, to quote a Rabelaisian simile, it is like endeavouring to elicit a sigh from a dead donkey to expect to excite any general interest on a foregone conclusion.

DR. BRUCE FERGUSON'S case of vertigo from tobacco is marked for early insertion.

A SUGGESTION IN RHYME.

A CORRESPONDENT sends us the following:

Tiny protozoa
Such as Clarke can see,
May be *causa vera*
Of malignancy.

DR. CRAIG.—We have the matter in hand, and hope to be able to deal with it next week.

MR. C. N. S.—Thanks for report, but the circumstances and all that concerns the case are so out of date that we could not refer to it at this period.

"DUCKING DAY."

ON the 17th inst. a coroner's jury at Plymouth returned a verdict of manslaughter against William Luscombe and Samuel Hine, two lads living at Loddeswell. In that village May Day is known as "Ducking Day," it being the custom for the boys, whenever they have the opportunity, to throw water over the passers by. Luscombe and Hine, from behind a hedge, threw a bucket of water at Dr. Twining, Medical Officer of Health, as he was driving through the village, to whose death, in consequence of the injuries he received from being thrown from his dog-cart, we have recently, with regret, referred.

DR. ALFRED SWANN'S letter is unavoidably held over.

Vacancies.

Bridgwater Infirmary.—House Surgeon. Salary £70 per annum, with board and residence. Applications and testimonials to the Hon. Secretary on or before June 15th.

Brislington House Private Lunatic Asylum.—Assistant Medical Officer (unmarried). Salary £250 per annum, with furnished apartments, board, and washing. Applications and testimonials to Dr. Bonville Fox, Brislington House, near Bristol.

County Lunatic Asylum, Lancaster.—Assistant Medical Officer (unmarried) also to act as Pathologist. Salary £100 per annum, increasing to £1[illegible]0, with board, &c. Assistant Medical Officer (unmarried). Salary £100 per annum, with board, &c. Clinical Assistant. No salary, but board, &c. Dispenser (unmarried). Salary £50 per annum, with board, &c. Applications and testimonials to the Medical Superintendent.

Earlswood Asylum for Idiots, Redhill, Surrey.—A fully qualified Practitioner (married preferred). Salary £500 per annum, with furnished residence, &c. Applications and testimonials to the Board of Management, 36 King William Street, E.C., on or before June 12th.

Flintshire Dispensary.—Resident House Surgeon. Salary £120 per annum, with furnished house, &c. Applications and testimonials to the Secretary on or before June 5th.

Jaffray Suburban Branch of the General Hospital, Gravelly Hill, near Birmingham.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing. Applications and testimonials to the House Governor on or before May 29th.

Liverpool Stanley Hospital.—Assistant Honorary Surgeon. Applications and testimonials to the Hon. Secretary on or before May 31st.

Stamford, Rutland, and General Infirmary.—House Surgeon (unmarried). Salary £100 per annum, with board, lodging, and washing. Applications and testimonials to the Chairman of the Special Committee on or before May 25th.

Victoria University.—University College, Liverpool.—Medical School.—Applications are invited for the George Holt Chair of Pathology. Endowment £375 per annum, together with share of fees. Also the Derby Chair of Anatomy. Endowment £375 per annum, together with share of fees. Applications and testimonials to the Registrar on or before June 2nd.

Appointments

BELL, T., M.D., B.Ch.Dub., Medical Officer for the Warrenpoint Dispensary District.

CULROSS, J., M.B., C.M.Glasg., Medical Officer of the Workhouse, Newton Abbot.

DOUGLAS, C. E., M.D., C.M.Edin., Medical Officer of Health for Cupar, Fife.

DURANT, W. J., M.B., B.S.Durh., Surgeon to the Hospital for Diseases of Women, Newcastle-on-Tyne.

FOSTER, J. R., M.B., M.S.Edin., Resident Medical Officer to the Cardiff Workhouse.

JONES, J., M.R.C.S., Surgeon to the Dewsbury and District General Infirmary.

LEATHAM, R. R., B.A., M.B., B.Ch., R.U.I., Assistant Resident Medical Officer to the North-West London Hospital.

MOLLOY, W. J., and MCAVOY, H., Senior and Junior House Surgeons to the Jervis Street Hospital, Dublin

MULLALLY, W. T., M.D., M.Ch., R.U.I., Dipl. San. Scie., R.C.P.I., an Hon Physician to the Ballarat District Hospital, Australia.

NESS, R. B., M.B., C.M.Glasg., Honorary Physician to the Royal Hospital for Sick Children, Glasgow.

NICOLL, J. H., M.B., C.M.Glasg., Honorary Surgeon to the Royal Hospital for Sick Children, Glasgow.

ORCHARD, J. S., M.D., C.M.Aberd., M.R.C.S., Visiting Physician and Surgeon to the Chorlton Workhouse.

PENNY, E. J., M.D.Brux., M.R.C.S., Medical Officer and Public Vaccinator for the First Sanitary District of the Tonbridge Union.

SARJEANT, J. F., M.R.C.S.Eng., L.R.C.P. Lond., Resident Medical Officer to the North-West London Hospital.

Births.

CRAMPTON.—May 14th, at Bond Street, London, the wife of T. H. Crampton, L.R.C.P.I., L.R.C.S.I., of a son.

DALISON.—May 16th, at Puddlestown, Dorset, the wife of Bernard E. Dalison, M.B.Ed., of a daughter.

JACOBSEN.—May 15th, at Ashwell Baldock, the wife of G. Oscar Jacobsen, M.R.C.S., L.R.C.P.Lond., of a son.

PRICKETT.—May 12th, at Oxford Square, the wife of Marmaduke Prickett, M.D., of a daughter.

RUSSELL.—May 13th, at Plås Alltran, Holyhead, the wife of William Fox Russell, M.B., Trinity College, Dublin, of a son.

SCOTT.—May 10th, at Fitzwilliam Square, Dublin, the wife of Dr. J. Harrison Scott, of a son.

SMYLY.—May 13th, at the Rotunda Hospital, Dublin, the wife of W. J. Smyly, M.B.Dub., of a daughter.

WEBBER.—May 13th, at Sutton Valence, Kent, the wife of Edward S. Webber, M.B.Cantab., of a son.

WILSON.—May 19th, at the Clock House, St. Leonard's-on-Sea, the wife of A. S. Wilson, M.B., D.P.H., of a daughter.

Deaths.

BROWNE.—May 17th, at Tulse Hill, Myra, eldest daughter of Robt. F. Browne, F.R.C.S.

DICKSON.—March 22nd, at Tarnagulla, Victoria, Australia, suddenly, Benjamin D. Dickson, B.A., M.D., T.C.Dublin.

GRAHAM.—May 12th, at Asfield Villa, Chamberlain Road, Edinburgh, Archibald Graham, M.D., H.E.I.C.S., late Deputy-Inspector-General of Hospitals, Bombay Army, in his 95th year.

HAMPSHIRE.—May 18th, at Jersey, F. Knowlton Hampshire, M.B., M.R.C.S., late Surgeon to the Straits Settlements, aged 50.

LEEPER.—May 16th, William Waugh Leeper, M.D., J.P., of Loughgall, aged 72.

SMITH.—May 10th, at Winnipeg, Manitoba, of scarlet fever, Walter Heywood, eldest son of Heywood Smith, M.D., of Harley Street, London, aged 21.

STONE.—May 14th, at King's Road, Wimbledon, Thomas Madden Stone, late of the Royal College of Surgeons, aged 79.

WARD.—May 17th, at his residence, Blyth, Northumberland, Gilbert Ward, F.R.C.S Eng., in his 90th year of age.

WEIR.—May 17th, at St. Mungo's, Great Malvern, Archibald Weir, M.D., F.R.C.S.Ed., aged 65.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

Vol. CVIII. WEDNESDAY MAY 30, 1894. No. 22.

Original Communications.

IS OPHTHALMIA SPREAD BY WASHING AND BY WASHING UTENSILS?

By SYDNEY STEPHENSON, M.B.,

Surgeon to the Ophthalmic School, Hanwell, W.

That ophthalmia may be communicated to healthy persons by the use of infected washing utensils is not an altogether modern view. As long ago as 1808, in his treatise *On the Purulent Ophthalmy*, James Ware[1] wrote as follows:—"The most natural explanation appears to me to be that this particular disorder is only communicable by actual contact; that is, by the application of some part of the discharge which issues, either from the tunica conjunctiva of an affected eye, or from some other membrane that secretes a similar poison, to the tunica conjunctiva of another person. That such a mode of communication did prevail in several of the regiments, in which the disorder raged with the utmost malignancy in the last year, is, I believe, admitted both by the surgeons who belonged to those regiments, and by the medical inspectors who were appointed to inquire into it. I can aver that the same effect has been produced by a similar cause in schools and in nurseries. In both of which, from inattention to a rule which I believe of much importance, though too little regarded, of hindering the hand basins and towels, which have been used by persons who have this disorder, from being employed by others, before they have been thoroughly cleansed, the ophthalmy has been communicated to nearly twenty in one school, and to the nurse, and several of the children in more than one family."

Ware has been quoted fully, as it would be difficult, even in the light of modern scientific knowledge, to state more clearly the usual mode of propagation of this contagious malady.

Three years later, Dr. Charles Farrell,[2] who saw much of the disease among the British soldiers in Egypt and in Sicily, expressed himself clearly on the matter. He remarked that "as it was necessary to prevent the communication of the morbid matter of the eye from one patient to another, each man was provided with a washing basin, and was strictly enjoined not to touch those belonging to others."

Writing in 1820, Dr. John Vetch,[3] Principal Medical Officer to the Ophthalmia Military Hospital, said:—"In the Army, such an ophthalmia has extended to whole regiments, without any appearance of the disease among the inhabitants of the neighbourhood, and . . . . the free intercourse that subsists among the men, as to washing in the same water, using the same towels, and sleeping more than one in a bed, readily accounts for the rapid extension of the disease." Vetch also remarked:—"In these barracks, as I have already observed, crowded to excess, the bedding, the water in which the soldiers wash themselves, and the towels which they use in common, presented so many ways of bringing the virus into action, that sleeping or waking, it was nearly impossible that its contact could be avoided."

Since the times of Ware, Farrell, and Vetch, many authors have adopted a similar attitude with regard to the spread of ophthalmia. Thus, in 1844, Lawrence[4] spoke of the necessity of isolating patients suffering from that disease, and of allowing an affected person to use none but his own cloths, sponges, and utensils. In 1854, Mackenzie,[5] dealing with the prevention of ophthalmia amongst soldiers, made this significant remark. "Barrack towels must afford a constant medium for the communication of this disease; they ought, therefore, to be discarded, and every man furnished with a towel for himself." In 1869, again, J. Soelberg Wells[6] wrote:—"The attendants must be warned that the discharge in catarrhal ophthalmia is contagious, and that sponges, towels, &c., used for the patient must be kept carefully apart, and not employed for any other purpose."

Recent writers are almost unanimous in their views as to the agency of faulty washing arrangements in the spread of ophthalmia. Thus Berry, Frost, Sandford, Juler, Dastot, De Schweinitz, and Von Arlt draw attention to the subject. Mr. Brudenell Carter[7] expresses his opinion in no uncertain way when he says that "experience seems to show that a practical community of washing arrangements is one of the most ordinary channels for the propagation of ophthalmia." Stevenson and Murphy, in their monumental work on *Hygiene and Public Health* (1893), advance a similar view. "The use of the same towel and basins, and an insufficient water supply are," they say, "the principal means by which the disease is spread, and their use may prove a danger not only to others but to the man himself by re-inoculation." The well-known Vienna Professor, Dr. Ernest Fuchs,[8] also, is emphatic upon the matter. "It has been positively ascertained," he writes, "that many epidemics have been caused by means of washing water and towels."

Those who have had to deal with ophthalmia in the Parochial Schools of the Metropolis have, almost without exception, insisted upon the danger of common washing. Dr. Mouat,[9] who reported to the Local Government Board in 1873, wrote as follows:—"The washing arrangements of the schools, however carefully watched and conducted, with basins and towels as at present supplied, are not such as to preclude the possibility of discharges from diseased eyes being brought into contact with those which are healthy. All children should wash at running taps, and the use of basins be discontinued in every school."

A year later, Dr. J. H. Bridges,[10] at that time Poor-law Inspector, added the following weighty testimony:—"The lavatories in pauper schools acquire special importance, because if imperfectly arranged they may be a very formidable means of propagating ophthalmia and other infectious complaints. When half-cured or convalescent children are mixed with the rest, the use of the same water or the same towel has, there can be no doubt, been a frequent source of infection." Much importance must be attached to this expression of opinion on the part of Dr. Bridges, who not only took great interest in the question of ophthalmia during a long official experience, but also enjoyed abundant opportunities of collecting evidence as to how the disease was spread.

Mr. Nettleship, however, seems to hold a different opinion. In his classical *Report on Ophthalmia in* *the Metropolitan Pauper Schools* (1874) he states that he has failed to trace any constant relation between the lavatory and washing arrangements, on the one hand, and the ophthalmic state of the schools, on the other; that those arrangements were well carried out, both in the institutions with the least and in those with the greatest amount of disease. After a careful review of the evidence, he is not disposed to attribute much importance to water as a vehicle for contagion, and he is further of opinion that the share taken by towels in this respect is less than many people suppose.

Any views coming from so distinguished an authority deserve careful attention. At the same time, one must not forget that the statistical method, on which he appears to found his conclusions, is surrounded with pit-falls. One fallacy may, perhaps, be pointed out, viz., that the greater the amount of the disease in any given school the more attention would naturally be devoted to the sanitary administration. We may thus explain the seeming anomaly that at Hanwell, where much ophthalmia existed, the supply of clean towels and of water was practically unlimited—unlimited, in short, because of the disease. After all, Mr. Nettleship's words amount, when analysed, to little more than a carefully guarded and qualified expression of opinion; and his failure to associate defective washing arrangements with the spread of ophthalmia cannot by any means be accepted as proof that the two conditions are not related in fact. His statements possess a negative value only. Anyway, it should be noted that Mr. Nettleship does not allow any theory of the kind to interfere with his views upon the point of prevention. His words are decisive enough on that score. "I hasten to add," he says, "that I should on no account allow the slightest relaxation of vigilance in respect to washing and bathing. I should make an abundant supply of clean water and towels, both for daily washing and for bathing, essential."

Thus far we have been dealing with individual opinions, rather than with ascertained facts.

At first sight it may, perhaps, seem curious that few observations, experimental or otherwise, have been recorded to show the connection between washing arrangements and ophthalmia. This omission is doubtless due to the fact that actual proof is not easy to obtain under ordinary circumstances; indeed, as regards the specific agency of water, it must necessarily be of an inferential nature. Towels, sponges, basins, and water form, after all, merely one of many means by which the seeds of infection may be scattered, and it would be difficult, if not impossible, to prove that in any given case they and they alone were to blame. Any conclusions in that direction must generally be arrived at by exclusion, rather than by other methods.

Towels and sponges would seem, *prima facie*, to be more likely agents in the spreading of disease than water; that they are so in point of fact is shown by a certain amount of direct evidence. For instance, the following case, which occurred in 1804 during an epidemic of ophthalmia in Chelsea Military Asylum, is recorded by Sir Patrick Macgregor.[12] A nurse, engaged in washing the eyes of a lad with ophthalmia, inadvertently applied the sponge that she had used to her right eye. This circumstance she mentioned to the other nurses, but she took no means to prevent infection. Eight hours after her eye began to feel uncomfortable, and next morning the disease was fully established. The eye was eventually lost. Another striking case is narrated by Delpech.[13] A young woman washed her eyes with Goulard water and a sponge, both of which articles had been previously employed by a youth suffering from gonorrhœa. Shortly afterwards she was attacked with violent ophthalmia, which speedily led to loss of sight. Tyrrell[14] records the case of a woman who occupied a room with her son, a young man, some 26 years of age, who had contracted a similar infectious disorder. She used a towel that had been contaminated by the young man, and in consequence contracted purulent inflammation of the eyes, which ended disastrously in three days.

Other instances of a similar kind are scattered throughout the literature of ophthalmia, and there can be little doubt that purulent disease has been commonly spread by indiscriminate use of towels, sponges, and other articles of that kind. It becomes impossible to deny that what is true of purulent ophthalmia may not be also true of any contagious eye disease accompanied by discharge.

It has been already remarked that evidence as to the actual agency of water in the spread of infection must be nearly always inferential rather than direct, suggestive rather than conclusive; in other words, that proof positive of such a connection cannot generally be obtained.

Vasani, at the commencement of the present century, succeeded in communicating ophthalmia to a dog by dipping it into water in which the eyes of two other animals labouring under the disease had been repeatedly washed. A similar kind of experiment was carried out by Van Roosbroeck,[17] who caused some patients suffering from purulent ophthalmia to bathe their eyes in a limited portion of water. The fluid was then divided into three parts, one of which was submitted to the action of heat, to another chloride of lime was added, while the third was neither heated nor treated chemically. Eyes afflicted with pannus were then innoculated. It was found that, while the first and second of the portions produced no effect, a single application of the untreated liquid never failed to induce the original malady. These experiments may be accepted, I think, as positive evidence of the existence of water-borne ophthalmia.

Piringer attempted to show that contagious discharges lost their infective properties when diluted with a sufficiency of water. According to his investigations, the most virulent pus is rendered inactive by the addition of 50—100 parts of water. It is more than doubtful, however, whether mere dilution would render impotent the germs to which purulent ophthalmia is certainly due. If we regard water as merely distributing the poison, it is less likely that a much diluted drop would contain any of the virus necessary to set up inflammation in an eye that it might reach. Nevertheless, Piringer's observations render still more difficult an already complicated subject, and cannot be disregarded when considering the question of transference by water.

It is quite possible that in some instances disease may spread not so much through the water as by means of infective particles that cling about the washing basin. But this is a mere refinement, and in practice it matters little which of the two methods might come into play. It will be sufficient for our present purpose to show that the common use of water or of washing basins is a source of danger.

Professor Snellen[15] has pointed out that one of the chief reasons for the continued prevalence of trachoma among the Jews of Amsterdam is connected with their ceremonial ablutions. The women, it appears, periodically bathe in common tanks, plunging their heads beneath the water. As many of the bathers suffer from chronic ophthalmia, Snellen says that this ceremonial observance becomes a frequent source of infection, contagious particles being conveyed by the water from eye to eye.

Dr. J. A. Marston,[16] has related some interesting and fairly conclusive instances in which the disease was spread through the agency of water. It appears that the malady was at one time so prevalent in the convict prison at Gibraltar that among the inmates of a particular dormitory one man alone escaped the infection. Being of a cleanly disposition, this individual never washed in the ward, but postponed his ablutions until such time as he could obtain pure water and plenty of it.

The facts of a second case are as follows. "The military prison was in a very crowded state, so that many prisoners had to be confined in the cells at Upper St. Elmo. These prisoners were not marched down to the lavatory of the prison, but washed out of two tubs, the water not being changed for each man, so that from 20 to 40 men washed in this water. A prisoner (Private S., 15th Regiment) was one of the first to suffer from ophthalmia, and the affected men of the Royal Artillery stated that they had washed in the water used by Private S. Until their then present attack they had never suffered from 'weak' eyes."

Perhaps, however, Marston's most conclusive case is the one to be now narrated. It may be given in the author's own words.

"A married officer, holding an important staff appointment, and residing in one of the largest and best houses in Valetta, sent for me to see one of his children suffering from ophthalmia. I was surprised to find that the child had vesicular lids, and still more so when I discovered that nearly the whole family had indubitably vesicular lids, mostly in a latent stage. The English nurse was affected, also the baby. I next discovered that a native wet-nurse had *lids advanced to a chronic and confirmed stage of the disorder*; the baby slept with her. The children were frequently bathed in the same water. An officer of the same department who had arrived but a few days at the station, was temporarily put up in the quarters of this affected family. His nurse and child occupied the same *day, but slept in a separate room*, and used *separate washing utensils*. They were perfectly free from the disorder. These facts leave no doubt in my mind that the native wet-nurse's lids were the *fons et origo mali* in the house."

The sole ambiguity in the foregoing case lies in the use of the term "vesicular lids." If by that expression Marston meant the contagious affection known nowadays as trachoma, there can be little doubt that his interpretation of the facts was the correct one.

Dr. A. Leith Adams[18] has published some analogous cases, of which the following may perhaps be quoted:—"One company of the 22nd Regiment was quartered, in 1864, in huts in an outwork of Floriana, Malta; there was no ablution room, and the only water supply was procured in buckets from a cistern distant about 200 yards in the ditch below. Now in this company there was a man who had suffered from granular lids, which were still discharging scantily with the mucous membrane in that thickened and abnormal state which may last for months or years after the disease has to all outward appearances been cured. In the course of a few weeks afterwards several cases of granular disease occurring among the men necessitated a careful inquiry into the probable cause or causes, when, in addition to what has been stated, it was shown that there had been a custom at early, or 'rouse parades,' in order to get through the morning ablution with dispatch, for sometimes six to eight men to wash in the same water, and dry their faces with each others towels." Adam adds: "I have numerous other examples tending towards a probability that ophthalmia is frequently communicated among soldiers in this way."

My own personal experience has furnished me with a number of instances where it was highly probable that ophthalmia was spread by water. Two such cases may be related, of which the first occurred some years ago under the following circumstances.

Two patients lay in the same ward. One of them was labouring under an attack of purulent ophthalmia, while the other was awaiting operation. The latter (whose eyes had been previously healthy) developed the disease, and it was then discovered that both had washed, on more than one occasion, in the same bowl and water, although separate towels had been used. The water, in this instance, seemed to have served as the medium for contagion: ophthalmia was the antecedent, ophthalmia the consequent.

By those who believe in aerial infection, my inference will perhaps be regarded as fallacious. As a set off to that hypothetical objection, I may add that during an extensive experience I have never seen anything to lead me to believe in the existence of air-borne ophthalmia. At the Ophthalmic School, which admits every kind of ophthalmia, no instance of contagion borne in that way has been observed. The institution has been occupied for four years, yet not a single nurse has contracted the disorder. None of the teachers, moreover, who are necessarily in close contact with the patients, have been infected. Lastly, I am aware of no instance in which disease has spread from child to child in any other way than by contagion, *i.e.*, by actual transfer of morbid particles. Had the disorder been capable of transmission through the air, it must surely, according to the law of averages, have attacked many of the individuals who, though exposed, have enjoyed complete immunity. The fact is significant that the precautions taken have been based upon the theory that ophthalmia is spread by the conveyance, direct or indirect, of specific discharges from eye to eye.

Shortly stated, the facts of the second case were these. A number of children occupied a detached building, which was divided into two portions, each possessing separate washing, sleeping, and day-room accommodation. Portion A was occupied by patients convalescent from ophthalmia, while B contained cases of the acute disease. The two groups of children were kept wholly apart. Acute ophthalmia broke out among those quartered in section A, and attacked in the first instance two patients who were ascertained to have stolen round and used the lavatory belonging to the other side. According to the statements of the two children, they had dried their faces with their own towels, which with curious perversity they had carried with them on the occasion of their surreptitious visit.

It may be objected that the disease which attacked the inmates of section A was the result of relapse, and that it had nothing whatever to do with infection. While admitting that such may have been the case, I cannot fail to regard the coincidence I have related as both striking and suggestive. It almost looks as if the children, in their mischief, had unconsciously planned the details of a roughly conditioned scientific experiment.

In the last instance which I shall mention it becomes difficult to say whether water or towels or both were instrumental in spreading the disease. The facts of the case are as follows. Towards the end of 1893 my advice was sought concerning an epidemic of ophthalmia among the inmates of a provincial school. The disease, of muco-purulent type, was practically confined to the girls and infants who washed in common at an insufficient number of fixed basins. The boys occupied another part of the establishment, and had their own lavatory. They suffered little, and that not until late in the history of the epidemic. Inquiry elicited the fact that in the first instance the disease had been brought into the school by an infant, and I feel confident that it was afterwards spread among the other girls and infants by means of the towels and washing basins which they used in common.

In addition, then, to the opinions of many distinguished writers, both ancient and modern, some amount of direct evidence exists to show that contagious eye disease is spread by defective washing arrangements.

Epidemic ophthalmia, it is well known, finds its *habitat* among closely congregated communities of persons. It affects, for instance, schools, orphanages, barracks, ships, penitentiaries, workhouses, and prisons, where it gives rise to infinite anxiety, annoyance, and expense. As regards schools, indeed, it has been shown that the malady attacks those of the highest as well as those of the lowest social standing. Quite recently the fact has been insisted on that some of the best public schools of this country are liable to occasional outbreaks of the malady, and Mr. Jonathan Hutchinson has emphatically stated his opinion that the disease is the same in the rich as in the poor. The unfortunate condition, both past and present, of many parochial schools in this respect is familiar to every reader of the newspapers, and need be mentioned only in this place.

The two foregoing propositions may be regarded, then, as established. They are, first, that the contagion of ophthalmia is often spread by imperfect washing arrangements, and, secondly, that the disease is apt to occur among any congregation of persons. The obvious conclusion is that absolute precautions should be adopted with regard to washing arrangements, so as to eliminate that common source of danger. Contagion may be conveyed in many ways, some of which are so obscure and difficult to trace that it becomes almost out of the question to deal with them efficiently. When we turn, however, to its transfer by faulty lavatory arrangements, we find ourselves on firmer ground. It is possible, for example, to provide against one and the same towel being used by more than one person; it is possible to erect such apparatus for washing and bathing as to render the use of water by more than one individual a physical impossibility.

The limits of this communication do not allow of detailed description of these arrangements and contrivances. The fact may, however, be added that such methods are in everyday use at the Ophthalmic School, Hanwell, W., and also at some other metropolitan institutions. In my own experience at Hanwell I have always found that they answer their end admirably, and they should, I think, be supplied for all communities of persons living together under a common roof.

London Post-Graduate Lectures

PHTHISIS AND LIFE ASSURANCE.

By E. SYMES THOMPSON, M.D., F.R.C.P.,
Consulting Physician to the Hospital for Consumption, &c., Brompton.

In the early days of life assurance the medical selection of lives was not attempted. The first life assurance society, "The Amicable," was founded in 1708, and existed for years before a medical officer was deemed needful. The same premium was paid by each applicant, whatever his age or however insecure his health. In process of time it was found desirable to exclude manifestly unhealthy applicants; hence it became necessary for the proposer to appear before the board. Some of the directors were shrewd in their judgments of the value of a life, but it soon became apparent that medical inspection was required for the selection of "first-class" lives.

The Clerical, Medical, and General Assurance Society led the van and began to receive "morbid lives" at an enhanced rate, the exceptionally strong medical element on the board enabling the office to conduct this responsible branch of insurance work with success. In some offices "invalid lives" make up a large and successful portion of the business of the office, whilst a few offices continue to refuse all but first-class lives.

As phthisis gives rise to 12 per cent. of the total mortality, it deserves the most careful attention from medical officers. The fact that among insured lives the mortality from phthisis is 8 per cent. shows that selection effects a material (4 p.c.) reduction. As the mortality from consumption occurs mainly in early manhood, it is essential for the stability of the office to detect and deal justly with this class. Half the mortality from phthisis among the assured occurs before the age of 40, and three-quarters before 50.

With degenerative disease, *e.g.*, gout, the risk is not a "diminishing," but an "increasing" one. The degenerative type is apt to involve descendants of the same sex; whereas phthisis involves both sexes, being especially marked among the sons of consumptive mothers. The conclusions drawn by Dr. Reginald Thompson from investigations at the Brompton Hospital, showing the very high mortality among the male descendants of consumptive mothers are not strongly confirmed by statistics obtained from selected assured lives. Paternal phthisical inheritance involves an excess of 23 per cent. above the expected deaths; maternal inheritance 25 per cent.; and, strange to say, maternal mortality in childbirth an extra risk of 28 per cent.

Statistics of the Mutual Office show that the death of collateral relations from phthisis has not been found to increase the risk or to alter life expectancy. Weismann's observations would prepare us to expect the death of brothers and sisters, uncles and aunts, and specially grand-parents, to have exercised a perceptible effect. It is probable, however, that a susceptibility or extra vulnerability is inherited rather than the disease itself; constitutional delicacy in the parent leading to susceptibility in the offspring.

Modern views as to the contagion and communicability of the tubercle bacillus tend to minimise the influence of inheritance, but the truth of heredity in phthisis is sustained by statistical evidence.

Among the symptoms of consumption, Dr. Symes Thompson showed that hæmoptysis was very serious in its effects. The class of cases accepted at the Equity and Law Assurance Society with an extra rating on the ground of hæmoptysis proved a very unfortunate class. Again, asthma, with its resulting emphysema and dilated heart had not been adequately covered by extra rating.

The difficulty of obtaining evidence to justify the acceptance of cases of phthisis in the first, second, and third stages was pointed out. A few instances were recorded in which such cases had been safely accepted with extra rating for short periods under the "endowment" or "limited payment" systems. A case of chronic cavity, with fibroid change at the apex of the lung, was detailed in which it was determined to accept the life, at a considerable extra rating, all premiums to be paid up in seven years. After the lapse of six years, the proposer being in good health and the evidence of lung disease less marked, it was determined to accept another proposal for ten years.

It may not be easy in insurance practice, when the opportunities for the examination of a case are limited, to make a prognosis with adequate confidence to justify the acceptance of a life in which there is serious organic disease. It must be remembered, however, that, with the advance of pathological knowledge, with accurate clinical methods and acquaintance with the natural history of disease, a prognosis may be made with such precision as to justify the acceptance of the risk.

In valvular disease of the heart the extra risks have been justly assessed, and in very many instances such lives have been safely assured. The same is true in regard to lung disease, and as experience increases such lives will be rightly received.

If each annual payment covers only a proportionate part of the sum assured very insecure lives may be insured without undue risk.

The statistics of the Washington Life Office show that medical selection has but little influence in diminishing risk after the first year. Of 353 deaths from phthisis during the first year of assurance.11 per cent. died ; second, 22 ; third, 24 ; sixth to tenth, 17 ; above ten years ,14. In English offices the results are much less unfavourable. The "New Mortality Tables" about to be prepared by the English offices will make plain many questions now obscure or unanswerable.

Sir Richard Quain stated at Cardiff, recently that the mortality in London had fallen since 1849 from 29 per 1,000 to 19, and the new experience would doubtless prove more favourable than that hitherto accepted as the basis of actuarial calculation.

Various medical forms used at different offices were considered. The elaborate and complex forms in use by the American offices may possibly draw out useful information from the various doctors in the U.S. and elsewhere to whom they were sent, but it was found best in England to apply only to highly qualified medical men, to ask them to fill up a short and simple form and to say clearly whether they recommended the life for acceptance or not.

A medical examiner should act in the closest sympathy with the actuary, but in his relations with the agent should exercise a discriminating caution.

The faculty of making reliable forecasts and accurate generalisations was a rare one. To adjust a suitable extra rating to meet a definite disease was comparatively easy, but to assess the degree of deterioration in a case of vague and ill-defined disorder was exceedingly difficult.

The chief medical officer was often obliged to "refer back" imperfect reports, to correct erroneous ones, and to be very watchful in taking note of omissions. Thus he was able to exercise a control over the selection of lives and greatly to enhance the value of reports which, when taken alone, could not be safely accepted.

◆

WHICH SHALL WE PERFORM,— CRANIOTOMY, CÆSARIAN SECTION, OR SYMPHYSEOTOMY?

By ROBERT P. HARRIS, A.M., M.D.,
Philadelphia.

There are many obstetricians at the present day, and their number is gradually upon the increase, who are opposed to craniotomy upon a living fœtus, and believe that the unborn infant has a much greater claim to be respected in the alternative of its mode of delivery than has in the past been accorded it. They regard this destructive operation as a relic of barbarism and believe that the mother should be subjected to some additional risk in order to preserve its life. With this end in view great efforts have been made in latter years to render the Cæsarian operation less dangerous to the life of the mother; and the much condemned one of symphyseotomy has been shown to have a legitimate claim upon our attention. It is very certain that these two operations can be performed with very little risk to the lives of the women, and that of the two, the section of the pubes has the lesser risk to the mother, while that of the abdomen and uterus saves the larger proportion of the children.

The possibilities of the two operations are best shown by the Cæsarian deliveries of Leipzig (1882-93), and the symphyseotomies of Italy (1886-93) all in Naples, but four. The number in each instance happens to be 54. The Cæsarian operations lost 3 women and 3 children, and the symphyseotomies 2 women and 6 children. Hospital success is far greater at the present day than that attained in private practice. If we honestly wish to know the capabilities of symphyseotomy we must examine the records of Profs. Morisani and Novi, of Naples, who have perseveringly tested it during 28 years. The claim that opening the pubes is apt to be followed by a want of union is entirely set aside by the results attained under pelvic fixation in Italy and the United States. As we have had 47 operations in this country we feel that we can speak from experience upon this point. The old claim that the pelvic conjugate gains so little in the operation that it cannot be of any practical value is entirely set aside in practice by the results with the forceps before and after section; theory is one thing here, and practice is another; the separation of the pubic bones gives in some cases much additional space.

Symphyseotomy is not as simple an operation as sometimes has been claimed, and the operator should handle both knife and forceps with skill. The subosseous incision of Naples, and adopted here, is far preferable to the direct incision of the French school, and is much more easy to dress after with a restraining apparatus. To make the prognosis favourable the patient should not have had a prolonged labour. Your country has never made a fair test of this operation, which is more of an alternate to the forceps and craniotomy than is the Cæsarian section. When you have had 10 symphyseotomies in England, performed under favourable prognoses, you may begin to talk of the method, from home evidence, and to reason understandingly upon its merits as a substitute for fœtal destruction. If these operations should be timely and performed with due care and skill, we have no fear as to their result in making the method satisfactory. New York City has had 10, and all of the women and children were saved except the first, mother and fœtus, operated upon *in extremis*. Ask any of her operators what he thinks of this method of delivery, and you may expect a favourable recommendation of it.

It is a very nice point to determine in some cases whether a fœtus known to be alive can be saved under symphyseotomic delivery or not, and whether under the feeling of doubt it will not be safer to perform the Cæsarian operation, and thus save it. This is very advanced obstetric surgery we admit, but I have twice advocated it in consultation; the proposal was adopted, and the women and children were saved. Personally, I have little fear of the Cæsarian operation, as the last eleven cases in which I was consulted, all recovered. Predetermined operations are rarely fatal in good hands in this country, and we are pleased to find that the fear of puerperal cœlio-hysterotomy is being very much reduced in Great Britain, through the successes of Prof. Murdoch Cameron, of Glasgow.

As home experience evidently has a most convincing effect in the British Isles we are anxious to get symphyseotomy fairly tested in London, believing that it will meet with favour, as it has here. Six members of the Philadelphia Obstetrical Society have operated sixteen times, and of these six, one has operated four times, and three others three times each, all in Maternity Hospitals. You cannot convince these obstetricians that symphyseotomy is not a valuable introduction, that there is any danger of its having a short-lived existence, or that opening the pubes carries a risk of producing lameness. By going back a century we can find arguments enough against the operation, but as we are in search of facts to encourage and to teach its present capabilities we are content to go back to January, 1886.

Note.—I spell "*symphyseotomy*" with an "*e*" as is done in Italy, France, and Germany, taking the term from the genitive.

◆

Selected Prescriptions and Therapeutic Notes.

141.—For Chloasma :—

℞ Hydrarg. perchlor., gr. x ;
Ammon. chloridi, ʒj ;
Sp. vini. rectificti, ℥j ;
Aq. hamamelid- dest., ℥iij.

M. A compress moistened in the solution is kept applied to the affected surface for a period of four hours. This produces a blister and the discoloured epidermis is replaced by one free from pigment.—John V. Shoemaker.

142.—For the Diarrhœa of Children :—

℞ Tinct. camph. co., ♏ xvij ;
Bismuthi subnitratis, ʒij ;
Syr. limonis, ℥ss ;
Mist. cret., ℥iss.

M. Shake well, and give one teaspoonful every three or four hours, to a child one year old.

143.—Useful in the Enteritis of Children :

℞ Ol. ricini, ʒj ;
Pulv. acaciæ, gr. xx ;
Sacch. albi., ʒss. ;
Tinct. camph. co., ♏ iv ;
Aq. anethi, ad ℥jss.

M. A teaspoonful every four hours for a child of one year.

144.—For Fœtid Feet :—

℞ Acidi salicylici, gr. xxx ;
Pulv. amyli, ʒv ;
Pulv. talci, ad ℥iij.

M. Dust in the socks.—J. C. Wilson.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, May 25th.

The President, Mr. Hulke, in the Chair.

ANNUAL MEETING.

The election of officers for the ensuing session was then proceeded with. Mr. Hulke was re-elected President, and Mr. Gould and Dr. Hale White secretaries.

The annual report showed the society to be financially in a flourishing condition. In consequence of the great interest shown by the members of the Society in the exhibition of living specimens, the Council proposes to devote the whole of at least three evenings each session to this branch of the Society's work. These meetings will commence at 8.30 o'clock and will close at 10. Members of the Society will be allowed to give notice to the Secretaries of their intenton to exhibit living specimens up to four days before the meeting, and a list of the specimens to be exhibited will be sent by post to every member in the United Kingdom. This change necessitated certain alterations in the laws and provisional regulations which were duly agreed to.

Dr. Churton on a case of

PANCREATIC CYST WITH DIABETES—ATROPHY OF PANCREAS—REMARKS ON TREATMENT OF THE CYST.

A man, æt. 35, was admitted into the Leeds General Infirmary on Nov. 28, 1892, complaining of pain in the abdomen and back, and intestinal rumblings. The epigastrium was prominent, and the pyloric third of the stomach, evidently pushed forward by a tumour behind it, splashed on palpation. The whole left hypochondrium was dull. The transverse colon was separated from the stomach by a dull area of varying width. The urine contained sugar ; its sp. gr. was 1033 ; its quantity was not yet markedly increased. The patient had become mentally and physically rather slow and weak ; his face and lips were pale. His family was not a robust one ; he himself had never been strong, but his three children were alive and well. He had never had any abdominal injury ; had been markedly dyspeptic for three years, and six months before admission, when there was influenza in his family, he had shivering, nausea, and pain in the epigastrium for several days, supposed to be caused by gall-stones. Exploration in the 8th left intercostal space in mid-axillary line found fluid of a dirty olive colour, containing very little ordinary albumen. A slight circumscribed peritonitis followed the puncture ; on its subsidence in a few days the patient was transferred to Mr. E. Ward for operation. Having made an incision in front, Mr. Ward drew off the fluid through a trocar, and then, having enlarged the opening in the cyst, passed his finger through the cavity to its posterior wall below the last rib, made an incision at that part for drainage, and closed the cyst and the wound in front. Dr. Arthur Clarkson, Demonstrator of Physiology in the Yorkshire College, gives the following (epitomised) analysis of the fluid : Slightly alkaline ; sp. gr. 1015 ; deposits red blood cells and leucocytes, the latter in the greater quantity ; some broken or ill-formed plates, doubtful cholesterine, serum-albumen, peptone, blood, pus, and mucin, but no sugar nor bile, found by chemical testing. Spectrum of methæmoglobin. No trypsin ; no fat-splitting nor milk-curdling ferments ; a starch-converting ferment (amylopsin) is present. The patient returned to the medical ward on Jan. 30, 1893, and was there treated with pancreas-extract, or liq. pancreaticus, and various kinds of diet, including grapes, one-third of a pound daily, which appeared to considerably increase the quantity of sugar in the urine. In February there was a trace of acetone in the urine. In March the discharge from the sinus, which had been clear and watery, became again purulent, but remained small in quantity until September, when it was increased, and there were signs of re-accumulation of pus behind the stomach. Purpura appeared on the feet and legs at this time. For two or three months he had been an out-patient, and improperly and insufficiently fed. Mr. Ward enlarged the sinus, liberating much pus ; but the suppuration afterwards, in spite of further incisions, spread behind the peritoneum, invaded the ureters and kidneys, and at length the patient died on Jan. 7, 1894. The pancreas was a mere mass of fibrous tissue, in which no trace of gland-tissue could be discovered by the microscope. In the duodenal end there was a very small cavity, apparently the remains of the former cyst. The duct could be slit up for about an inch and a quarter from the junction with the bile-duct in the papilla, when it stopped abruptly at a thick fibrous wall. There was no calculus. Three small branch-ducts could be traced from it ; they also ended in fibrous stroma. The thin body of the organ was composed of vessels and fibrous tissue. With respect to the treatment of pancreatic cysts, surgical opinion seemed to favour incision rather than aspiration, but the author, instructed by the present instance, considered aspiration preferable in cases associated with glycosuria, since—(1) the glysurin is a sign that the pancreas has become atrophied ; (2) that being so, it does not appear that life can be much prolonged, even with the aid of pancreas-extracts; (3) diabetic patients are more likely to become a prey to septic organisms; (4) pancreatic cysts have been cured by aspiration; (5) in eight successful cases treated by incision to which the author had been able to refer glycosuria was not present; (6) he had not been able to find records of any successful cases in which it existed.

The **President** observed that stress was usually laid upon the nature of the cyst contents in arriving at a diagnosis, but though this might possibly be of some value in new cysts it did not hold good of older cyst formations. For operative purposes he divided these cysts into two groups, first, those which were stalked and connected with only a small portion of the pancreas. These could easily be drawn up and drained. Secondly, those which were more or less sessile, and these were much less easy to deal with.

Mr. A. **Pearce Gould** said that since the publication of his two cases referred to by the author he had seen a third case, the main symptom was marked jaundice. There was a tumour about the size of the fist in the epigastrium which he cut down upon and drained. On the third day after the operation the patient sank and died with symptoms of commencing peritonitis. They were permitted only a partial post-mortem, and they had not yet had time to thoroughly dissect the specimen. There was a large cyst involving the head of the pancreas and the common bile duct lay over it, very much flattened, indeed hardly recognisable. In his opinion aspiration of these cysts was necessarily a rather dangerous proceeding. He had never done it himself, but having opened three such cysts in addition to having assisted at the opening of another he said that in every instance he was thankful that he had not attempted aspiration, for it would in every case have exposed the patient to the risk of wounding one or more of the large vessels running in front of the cyst, the stomach, or the duodenum. He pointed out that the contents of such cysts were usually too thick to come away freely through an ordinary aspirator trocar, and he repeated that the aspiration of abdominal cysts was unnecessary and dangerous. With reference to the indication afforded by concomitant glycosuria he suggested that in the presence of marked glycosuria it would be preferable to let the case alone. Such cysts, moreover, refilled with great rapidity, and no one would regard repeated aspiration as a safe or desirable practice.

Mr. **Wallis** said he fully concurred in regarding as undesirable the practice of aspirating abdominal cysts which was not a surgical procedure. In one instance at any rate he had seen alarming symptoms follow.

Dr. **Churton**, in reply, said he only looked upon aspiration as a *pis aller*. He had been very much impressed by the failure of the operation in his case especially as such patients were peculiarly liable to take on septic changes as shown by the fact that suppuration followed an attempt to collect some of the fluid for analysis. He pointed out that hydatids were sometimes cured by a single aspiration, and in most text-books it was stated that in certain instances cysts of the pancreas have likewise yielded to a single puncture. If this were so then he thought it was worth trying. If, on the other hand, aspiration always failed to afford permanent relief in diabetic patients he agreed that it would be better to leave such cases alone.

Dr. **Sansom** on a case of

PURPURA HÆMORRHAGICA WITH ACUTE PEMPHIGUS, PROBABLY INDUCED BY INFLUENZA.—TREATMENT BY LARGE DOSES OF SODIUM SULPHOCARBOLATE.—RECOVERY.

A girl, æt. 12, was admitted into the London Hospital, November 15th, 1893, in an extremely feeble and critical condition. Extravasations of blood were seen about the eyelids; there was much oozing of blood from the mouth; hæmorrhagic stains and spots were observed on the skin covering the chest, abdomen, back as well as upper and lower extremities. Bullæ (as of pemphigus) containing deeply blood-stained fluid were upon the left ala nasi, over the abdomen, the arms and the legs. The tongue, generally stained darkly, presented several small bullæ over its dorsum and sides; like blebs were seen within the lips, all containing blood-stained fluid; some bursting and liberating their contents to produce oozing from the mouth. There was vomiting, the vomit being blood stained and much blood was voided with the evacuations. The urine contained a trace of blood. The pulse, 124; respiration, 34 per minute · cough with deeply blood-stained sputa; bronchitic râles heard on chest front and base of right lung. The temperature on admission was 98·8° F., but rose on the day following to 103·8° F. Half-drachm doses of sodium sulphocarbolate were administered every four hours. During the next five days, the patient was in a very critical condition, the signs being little changed. After nine days, though there were indications of some general improvement, hæmorrhagic extravasations were observed on each fundus oculi with signs of double optic neuritis. There was, however, continuous amendment, though temperature rose on one day to 105° F., and on the next, to 104° F. All the morbid signs passed away, and the patient was discharged quite well after having been in the hospital for thirty-six days. It was thought probable, considering the mode of onset and the accompanying pyrexia, that the disease in this case was due to an infective agency. Collateral evidence showed that influenza might be attended with the signs and symptoms noted. In a well-marked case, the administration of sodium sulphocarbolate in half-drachm doses every four hours for a protracted period had been practised, and the patient completely recovered. Encouraged by this, Dr. Sansom adopted the like plan of treatment in the case now brought forward; the recovery was equally satisfactory.

Dr. E. **Diver** on

THE USE OF CHLORINE GAS IN THE TREATMENT OF CHRONIC ULCERS OF THE LEG.

The cases of two aged widows in the lower ranks of life formed the subjects of treatment. The gas used was formed by pouring about 2 drachms of potassium chlorate, ʒi or more of HCl in a pickle or marmalade jar, the outside of which was covered by brown paper. After this a disc of white paper was introduced, and on top of the paper a sufficiency of absorbent wool; a large cork was then fitted to the neck of the jar. The wool, yellowish green on the surface when at first exposed to view, was then placed over the ulcer in each case, and quickly covered by gutta-percha tissue; then the patient was left to do in the way of bandaging or covering what she had been used to. No rest was enjoined. The gas was probably chiefly Cl with some peroxide of Cl in mixture.

Patient H. had on commencing treatment a varicose ulcer on each leg between the calf and the ankle. Both steadily improved under treatment, and the left was well by the 28th January, 1894, having been under treatment eight weeks, and the dressing having been applied three times weekly. This leg had never been healed for 25 years; and at the time of commencing treatment was over 2 inches long by nearly 2 inches broad. The second ulcer is now nearly well, but its progress was impeded by an accident, and by several other circumstances.

Patient A had a large annular ulcer which originated in a cat bite some 20 years ago. Its boundaries were from a little above the ankle to near the middle of the calf, and were very deep. This was treated in exactly the same way, and soon its ashy surface showed granulations, which went on increasing until the level of the skin was reached in the middle of January, after six weeks' treatment. Since the ulcer has maintained its granulations, and narrowed very considerably its area; and is now steadily improving. The patients were exhibited to show their present condition. And drawings of the ulcer in patient A were shown to illustrate its appearance on the commencement of treatment, and on the 7th of April last.

After some remarks by the President and Dr. Benham, the author said that he had been led to try chlorine gas by observing the extraordinary way in which it increased the germinating power of poor samples of barley. This had induced him to employ it as a local stimulant.

LARYNGOLOGICAL SOCIETY OF LONDON.

Ordinary Meeting held May 9th, 1894.

Felix Semon, M.D., F.R.C.P., President, in the Chair.

LUPUS OF NOSE AND LARYNX.

Dr. **Dundas Grant** showed a patient who had suffered from hoarseness for two years, unaccompanied by pain, but with increasing obstruction of the left nostril. There was no pulmonary disease nor any family or personal history of phthisis. The disease affected the tip of the nose, the cheek, the soft palate, the posterior wall of the pharynx, the epiglottis, ary-epiglottic folds, and ventricular bands. A soft mass in the inter-arytænoid fold prevented the approximation of the vocal cords. The patient was being treated by scraping and the application of lactic acid, and was taking arsenic internally.

PROBABLE EPITHELIOMA LARYNGIS.

Dr. **Dundas Grant** showed a patient, æt. 67, a retired schoolmaster, who had suffered from hoarseness for three years. No cough and but very slight dysphagia, hard and hot things being swallowed quite easily. There was no dyspnœa, and no indication of thoracic disease. The thyroid cartilage was not expanded, and there was no enlargement of lymphatic glands. The whole length of the left vocal cord was occupied by a pale pink slightly granular ulcer the surface of which was somewhat convex in its middle part. The cord was fixed immovably in the middle line. The rest of the larynx was comparatively normal. The case was thought to be one of intrinsic carcinoma, from the appearance of the cord, the fixation of the arytænoid cartilage, and the age of the patient. The case seemed a favourable one for thyrotomy and partial removal.

The **President** thought that it could only be dealt with by thyrotomy. The extent to which removal should be carried must be determined after the thyroid had been opened.

PARALYSIS OF THYRO-ARYTÆNOID MUSCLES.

Dr. **Dundas Grant** showed the case of a post-office clerk who had suffered for three years from hoarseness unaccompanied by cough, dysphagia, or dyspnœa. No other disease or history of disease could be made out. The respiratory movements of the larynx were normal, but on phonation there was a very marked elliptical gap between the edges of the cords, except at their most anterior and at their arytænoid portions. The ventricular bands approximated to an extreme degree, and probably shared in some of the production of the voice, which was continuously husky and low pitched, but the patient could produce hoarse whispering tones ranging through nearly three octaves. The crico-thyroid muscle appeared to be acting well.

Dr. **Spicer** thought that at one point there was thickening and chronic inflammation much resembling the condition of pachydermia laryngis, and suggested that the whole of the symptoms might be explained by its presence.

The **President** had not observed any inflammatory changes, and thought that the case was paralytic in origin, but suggested that the case should be kept under further observation.

REMOVAL OF RIGHT LOBE OF THYROID FOR GRAVES' DISEASE.

Mr. R. **Lake** showed a patient, a young woman, who had suffered in 1893 from symptoms of Graves' disease, and from whom he had removed the right half of the thyroid gland and the isthmus. Relief to many of the symptoms had been complete. The remaining lobe appeared to have shrunk considerably. Microscopically the goître was partly composed of small cysts and partly of acini showing active cell formation as described by Greenhill.

The **President** suggested the possibility of the subsequent occurrence of myxœdema, and it was decided that the case should be seen again during the ensuing autumn session.

Dr. **Spicer** commented on the occasional failure of tablets of thyroid extract in the treatment of these cases.

Mr. **Lake** had met with successful cases so treated.

LUPUS OF PHARYNX AND LARYNX.

The **President** showed the case of a girl, æt. 10, who had complained of loss of voice for three months and ulceration of gums and palate for two months. Family history good, no syphilis, tuberculosis, or rheumatism. The gums, the roof of the mouth, the posterior palatine arches, the epiglottis and the ventricular bands were all affected with a rough uneven granular ulceration, in places partly cicatrised. There was no pain either in the mouth or the larynx, nor were there traces of any affection of the skin or nares. The case would be treated by scraping, application of lactic acid and possibly by the galvano-cautery, arsenic and cod-liver oil being given internally.

TWO CASES OF DOUBTFUL MALIGNANT DISEASE OF THE LARYNX, TREATED BY THYROTOMY AND RADICAL REMOVAL OF THE GROWTHS.

The **President** showed these cases. In neither had the diagnosis of malignancy been established beyond doubt, but in both it was deemed prudent to perform the radical operation. Case 1.—A gentleman, æt. 63, with an ill-defined papillary growth on the anterior half of the right vocal cord, the anterior commissure and the front part of the left vocal cord. Repeated recurrence had taken place after intra-laryngeal removal, and therefore all the parts affected were removed by thyrotomy. No recurrence had taken place. The growth was papillomatous with extraordinary horny thickening of the epithelium covering it. Case 2.—Colonel G. W. H , æt. 55, in whom a reddish growth on the left vocal cord had gradually spread and infiltrated the whole cord, producing an almost uniform thickening. The cord was removed and the basis scraped. At Mr. Butlin's suggestion (Society's "Proceedings," pp. 27, 28) Hahn's tube was removed immediately after the operation and no other introduced. The patient was kept strictly horizontal but on one side. He made a rapid and uninterrupted recovery. A further report would be presented as to the exact microscopic conditions of the parts removed. Special attention was called to the difficulty of dealing with the doubtful cases, from which it was not possible to remove portions of the growth for preliminary examination. The suggestions made by Mr. Butlin as to the slow use of Hahn's tube, its removal after the operation and the leaving of the wound completely open while the patient remained in the horizontal position had made exploratory thyrotomy so much simpler and easier that it might safely be adopted as the operation of the future for dealing with these cases.

SEQUEL TO A CASE OF OBSCURE ULCERATION OF PHARYNX IN A CASE OF ARRESTED PULMONARY AND LARYNGEAL TUBERCULOSIS.

The **President** showed a case which had already been described ("Proceedings," p. 74) in which pharyngeal ulceration had resisted treatment by scraping and the use of lactic acid, which had completely arrested the similar disease in the larynx. Examination of scrapings from the pharyngeal ulcers had failed to show the presence of tubercle. The ulceration had healed of itself, and the patient stated that it had done so before, hence its exact nature was still doubtful. Creosote had been given internally in large doses, and much of the success of the case was attributed to its constant use.

Dr. **Dundas Grant** agreed that creosote had formerly been given in much too small doses.

Dr. **Clifford Beale** quoted the experience of the Chest Hospital practice, where creosote had been given very freely both in large and small doses, and also in concentrated vapour. It appeared to be singularly well borne even by the delicate stomachs of tubercular patients, but there was as yet no positive evidence to show that in the cases of rapid and active disease any marked effects were produced.

FIXATION OF LEFT VOCAL CORD.

Dr. **Scanes Spicer** showed the case of a widow who for several years had suffered from hacking cough and hoarseness, aggravated by exertion. A history of infection with specific disease shortly after marriage, and the absence of any other indications, led to the diagnosis of fixation by ankylosis of the crico-arytænoid joint.

UNILATERAL LARYNGITIS.

Mr. W. R. H. **Stewart** showed a patient suffering from loss of voice due to redness and swelling of the right vocal cord and puffiness of the arytænoid cartilage. This had been temporarily increased by the use of steam inhalations at too high a temperature, producing an appearance similar to that seen in tubercular disease, but no evidence of actual tubercular disease could be obtained.

PROBABLE MALIGNANT DISEASE.

Mr. W. R. H. **Stewart** showed a patient, æt. 50, a gardener, with considerable swelling of the right side of the larynx and some glandular enlargement on both sides. The symptoms were chiefly soreness, dyspnœa, and dysphagia.

The **President** would limit operative interference to the intrinsic cases. Luschka had shown that the lymphatics of the larynx do not anastomose with other sets of lymphatics, but lead directly into two small glands close to the thyroid. Hence in the intrinsic cases there was so much less lymphatic enlargement. Where other lymphatics were involved the disease generally recurred.

Dr. **Bond** agreed with the President's views.

Dr. **Spicer** pointed out that disease had sometimes been thought to be intrinsic, but on operation had been found to extend beyond the limits.

CONGENITAL ABNORMALITY OF THE LARYNX.

Dr. J. B. **Ball** showed a patient the subject of an enlarged and apparently displaced left arytænoid cartilage, which passed in front of its fellow on phonation, but without any disturbance of vocal function.

Dr. **Watson Williams** (Bristol) exhibited a form of syringe adapted for submucous injections within the larynx, made by Messrs. Down Brothers for him.

Dr. **Bond** showed a case of Malignant Disease, and a case of Growths in the Nose and Naso-pharynx.

◆

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, May 27th.

Pseudo-elephantiasis (neuropathic) of the Arm in an Hysterical Patient.

At the last meeting of the Société Medicale des Hopitaux M. Thibierge showed a patient affected with a variety of œdema of which cases are rare enough to deserve attention. By reason of the hysterical symptoms exhibited by the patient the question suggested itself whether the œdema also did not arise from the same neurosis. Besides cases in which it assumes the form well known from the description of Charcot (œdéme bleu) œdema of hysterical origin can—as in the observations recorded by Weir Mitchell—present the common appearances of acute œdema involving an entire limb. There was, however, some difficulty in the present case in placing the œdema among the symptoms of hysteria because its appearance did not coincide with the hysterical manifestations, and because the affected member was not the seat of either contraction or paralysis, symptoms which usually supervene upon hysterical œdema. It seemed rather that the main neurosis and the œdema merely coexisted, and each separately indicated the same neuropathic tendency in the patient. Three similar recorded cases were referred to in M. Thibierge's note.

Pigmentation of the Skin during Exhibition of Arsenic.

At the same meeting M. Richardiere showed a patient in whom Fowler's solution administered during only four weeks had caused a very marked brown pigmentation of the skin. The doses had been gradually increased, and the pigmentation displayed itself first on the 18th day. In a few days it became well marked. It affected the skin only, not the mucous membranes. It was much more marked in some regions than others. These were the axilla, the neck, the dorsal aspect of the fingers and toes. There existed also a large number of pigmented lenticular spots which appeared at parts where the skin had been previously bitten by insects or wounded in similar ways.

Cancroid of the Face.

At the meeting of the Academie de Médecine, M. Darier related a series of cases of cancerous tumours of the face rapidly cured by the daily application of a 5 per cent. solution of blue of methylene. This agent appears to be a regular specific upon the cancerous element; however, the effect is much more marked if the affected part be cauterised previously with chromic acid, or with the actual cautery.

In deep-seated tumours, the methylene blue should be employed in subcutaneous injections. M. Meyer cited also several cases which he had treated with the agent in question, and which were very quickly cured.

Lesions of the Stomach Simulating Cancer.

M. Ferrier drew the attention of his colleagues of the Surgical Society to a form of gastric disorder simulating cancer, and which was much ignored in a surgical point of view in France. A woman entered the hospital with gastric troubles, presenting all the symptoms of cancer and coinciding with the existence of an epigastric tumour. M. Ferrier performed laparotomy for exploring purposes, and found the stomach adherent to the walls of the abdomen, and to the left lobe of the liver. After breaking down those adherences, the operator closed the wound, and the patient gradually lost all bad symptoms, and left the hospital quite recovered. In concluding, M. Ferrier said that in many cases, purely inflammatory lesions could simulate cancer, and an exploring operation would put the case in its true light and do no harm to the patient.

[FROM OUR OWN CORRESPONDENT.]

Berlin, May 25th.

THE SURGICAL CONGRESS.

On the third day of the Surgical Congress, Crédé, of Dresden, spoke on

The Technique in the Larger Amputations.

He said he had not found Esmarch's bloodlessness suitable in all cases, and thought that when constriction was not practised fewer vessels required ligaturing. For this reason he avoided the elastic bandages, and also suture and drainage. His principal attention was bestowed on the accurate coaptation of the edges of the wound and equable compression by gauze bandages. By this means the edges of the wound became quickly glued together. In forming the flap the muscles were also made use of for the purpose of assisting in the nutrition of the stump. In the 22 cases in which this method had been practised recovery had been surprisingly rapid. All healed by primary intention, and in ten days the stump had become firm and free frcm tenderness.

In the discussion that followed, both Profs. Gussenbaum and v. Esmarch agreed with the speaker.

Dr. Bier, Kiel, next spoke on

The Treatment of Surgical Tuberculosis by Stasis Hyperæmia.

Starting from the observation that very vascular organs were generally free from tubercle, he had attempted to bring about an artificial hyperæmia in tuberculous joints by artificial blood stasis. The results of his treatment had been exceedingly good, as the hyperæmia produced by constriction contributed to a better nourishment and a greater power of resistance of the affected parts.

Prof. Mikulicz, Breslau, said that he had frequently made use of the method in his klinik, and confirmed the favourable statements of the previous speaker. Whoever had seen the results obtained must arrive at the conviction that the method was an excellent one, and many operations would be avoided by its use.

Dr. Zeller, Berlin, who had also tried the method, had not met with such favourable results. He had only observed complete recovery in one case of recent tubercular joint mischief.

Dr. Barth, Marburg, discussed the subject of

Osteoplastics from a Histological Point of View.

He said that the implantation of bone free from germs or even ivory could only succeed in so far as the material implanted became absorbed, and was replaced by new bone, formed the periosteum of the old bone. The process was the same as when a piece of living bone was excised and immediately replaced. The piece of bone implanted could come into organic connection with the living bone and take on the function of the lost piece.

Prof. Helferich, Greifswald, showed numerous sections of bones of rabbits in which the intermediate cartilage removed and then replaced had not lost its function as regarded the continued growth of the bone.

Prof. Bramann, Halle, showed a man who had suffered such comminution of the humerus that there was no prospect of saving it from amputation. He attempted, however, to save the arm, and took a piece of bone from the tibia, putting it in place of broken section removed, with the fortunate result that complete union took place.

Dr. Riecheval then related a case treated by Prof. Bardenhauer, Cologne, of congenital defect of the radius in which the ulna was split along its whole length. the two halves separated, one half serving as the original bone and the other taking on the functions of the missing radius The carpal bones were adjusted in connection with the severed ends of the split bone.

On the last day of the Congress the

REPORT OF THE COLLECTIVE INVESTIGATION COMMITTEE ON ANÆSTHETIA

was received. Prof. Guech, Berlin, in presenting the report said on the proposition of the society he had carried out the investigation to a fourth year. In 1893 63 reports had been received, of which 9 were from abroad. 15 reports had been sent from 21 German University Kliniks. The total of last year's cases was 51,846. Of these 32,723 were chloroform administrations, 11,617 of ether, 3,896 with ether and chloroform, 750 with chloroform, ether and alcohol (Billroth's mixture), 2,769 with bromide of ethyl, 91 with nitrous oxide. The total fatalities was 20, and of these 17 were due to chloroform. The average death-rate was 1 in 2,587 administrations. The death-rate from chloroform was 1 in 1,924. When the results of the previous year were added the totals were 163,493 administrations with 61 deaths. The rate of mortality was: chloroform, 1 in 2,655; chloroform and ether, 1 in 8,014; Billroth's mixture, 1 in 4,890; bromide of ethyl, 1 in 3,662; ether, 1 in 26,268. In fact only one death had occurred from ether narcosis, and that was a case of heart disease. In correspondence with the low death-rate from ether, its employment had largely increased of late years from 6,200 in 1892 to 11,600 in 1893. Pichet's purified ice chloroform had been used 3,890 times with 2 deaths, so it would appear that the dangers of chloroform inhalation did not lie in any accidental impurity, indeed the facts seemed to point the other way, and that the danger was directly proportionate to the purity of the chloroform. This consideration had lately led to a different mode of administration. It had been given more slowly, and occasionally atropia and cocaine had been used with it. As regarded accidents 255 severe cases of asphyxia had occurred, and tracheotomy had to be performed three times. König's cardiac massage, so-called, was frequently used, but not always with success. Ether had therefore shown itself the least dangerous anæsthetic, ten times less dangerous than chloroform, but it was not without its shady side. It was dangerous in lung affections. It was agreed to still continue the investigation.

◆

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 25th.

SPERMATOCYSTITIS GONNORRHOIEA SUPPURATIVA.

REICH showed a young man to the "Gesellschaft" who came to him with a swelling of the right testis and pain along the seminal duct, which he stated had come on after a severe attack of gonorrhœa. On examination, per rectum, the prostate was small, but beyond it was very tender and tense to the touch far beyond the reach of the finger. Eight days later suppuration was observed to come away from this part by gentle pressure, and prostatectomia lateralis was thereupon resolved on as the best treatment. The opening was made on right side, the bowel carried towards the left, and a portion of the ischia removed till the abscess was reached, which was found in the vesiculæ seminalis. The fever disappeared, the bowels acted regularly, while the wound rapidly headed by the application of tampons.

He remarked that 18 cases were already recorded in literature, 6 of which had occurred after gonorrhœa, 2 from traumatic causes, and 10 the nature of which are not stated. In some of the cases the patient is described as passing red-brown sperma with painful ejaculations; but Reich's case had none of this. This method of reaching the vesiculæ seminalis was performed according to Dittel's for reaching the prostate, but Dittel, who was present, said that, however advantageous his operation is in reaching the prostate, he questions the advisability of performing it in such cases affecting vesiculæ seminalis.

STRUMA.

Schnitzler showed a preparation from a woman, æt. 31, who died the previous day shortly after the operation. She came to him with all the symptoms of morbus Basedowii and the thyroid greatly enlarged and impeding respiration. Strumectomia was decided on as the only permanent relief for her. Owing to the size of the gland the operation took hours, but no extra amount of blood was lost. The right side and enormously-enlarged middle lobe was removed entire with a portion of the left lobe. During the dressing the patient became pale, the breathing quiet, which recovered on way to bed; fifteen minutes after being placed in bed the respiration suddenly ceased in rhythm and became stertorous, the pulse slow, but regular, and the pupils contracted; shortly afterwards the breathing ceased, the pulse slower, and the pupils dilated to the extreme. The obduction revealed Paltauf's "Status thymicus;" all the lymphoid glands were greatly enlarged as tonsils, folicules of bowel and spleen. In addition to this a slight narrowing of the aorta was present with dilation of the heart, while the marrow of the long bones was greatly reddened. This peculiar condition has been shown by Paltauf to be the proximate cause of death occurring suddenly after or during the operation, which is more plausible than narcosis, &c. This view of sudden death appears to be confined to Vienna, and is supported by incontestible evidence by Albert and Kundrat. This case is the third sudden death within a very brief period, and all of them with similar post-mortem symptoms. Ghick attributed the death of his case to the pressure of the large thymus on the respiratory organs, as it occurred immediately on commencing the operation, while the death of Bardeleben's case occurred shortly after the operation. Schnitzler considers both of the cases were due to Paltauf's "Status thymicus." As this condition is frequently associated with morbus Basedowii, he thought the indications for surgical interference were negative. Paltauf said that the thymus was a sure symptom of the state of other glands which arise from different causes. He has found the thymus persistently enlarge with all the other glands after drink and chloroform where sudden deaths have occurred. The enlarged thymus must always be accepted as the indication of general glandular changes when associated with anæmia and narrowing of the aorta. He agreed with Schäffer in thinking that all the lymphatics take on a hyperplastic form concurrently. A persistent thymus, constantly increasing, would, therefore, be a signal to measure the entire constitution which is manifested by the persistent anæmia.

Eisenschutz observed that he had seen cases of enlarged thymus in children who had passed through the asphyxia stage of cholera. He considered some connection to exist between deaths from chloroform and cholera. He did not believe in compression of the trachea, but thought that changes in the blood with chlorosis had much to do with the exitus. In these persons a kind of vulnerability existed.

◆

THE special usefulness of a medical magistrate was illustrated last week at Faversham. A workhouse inmate was arraigned before a medical J.P., charged with refusing to work, to which he pleaded that he was the victim of heart disease, whereupon the magistrate promptly descended from the Banch, produced a stethoscope, auscultated the culprit, and reascending the throne of justice, sent him "up" for seven days for malingering.

IT is proposed that the British Medical Association shall hold its meeting of 1895 in London.

GENERAL MEDICAL COUNCIL
OF
EDUCATION AND REGISTRATION.
SPRING SESSION, 1894.

The President, Sir Richard Quain, Bt., in the chair.

FIRST DAY—Tuesday, May 22nd, 1894.

After the usual Presidential Address sketching the work which awaited the Council, it was resolved, on the motion of Mr. Carter, to sanction a scheme submitted by the Society of Apothecaries providing that the assistant examiners in surgery should retire in rotation and should not be eligible for re-election until after the lapse of two years. In virtue of this scheme Mr. Walsham retires and Mr. Bernard Pitts takes his place.

Medical Aid Associations.

Mr. Bryant called attention to the rapid increase in the number of medical aid associations conducted by laymen for profit, and he directed the attention of the Council to the injurious influence which, in his opinion, such associations have upon the public as well as upon professional interests, and he moved that the matter be referred to the legal advisers of the Council to consider whether these associations were properly registered under the "Friendly Societies Act (1875)." He based his arguments on the degradation attending the placing of a professional man in the position of a paid servant of a trading company, thereby rendering it obligatory on himself to attend medically people who had no claim to be treated on charitable or inadequate terms. He contended, moreover, that such a practice tended to degrade the high character of medical science as represented by the officers of such institutions, working as they did under conditions which were not only humiliating, but which made it difficult for them to efficiently perform their responsible duties.

Sir Dyce Duckworth seconded the motion.

Dr. McVail, without entering into the merits of the question at issue, urged that the legal point raised by the motion did not belong to the Council to decide, their duty being only to protect the public against incompetent practitioners.

Sir Walter Foster endorsed this view on the ground that it was for the public to take action in the matter. He admitted, however, that medical men accepting such appointments might be construed to be guilty of infamous conduct in a professional respect, and he suggested that a better way of re-opening the subject would be to re-appoint Dr. Glover's Committee for the purpose of framing a resolution which could be submitted to the Council.

Dr. MacAlister, as a member of that Committee, asked to be excused should this course be decided upon in view of the fact that the conclusions so laboriously arrived at by the Committee had been rejected by the Council. Moreover, he failed to see that there were any new facts to justify the matter being once again referred to the Committee, and if any action were to be taken it could only be on the report already presented to the Council. He pointed out that the mover and seconder of this very motion had voted against the adoption of the report.

Dr. Leech, also a member of the Committee, thought it would be a mistake for the Council to go back on their decision of last year, and he dissented from the view that the holding of such appointments amounted to infamous conduct.

Mr. Bryant explained, in justification of his change of front, that much additional evidence had since been obtained of the injurious tendency of these associations. Personally he took the view that the conduct of persons accepting such appointments constituted infamous conduct in a professional respect.

Dr. Wilks regarded the question as merely one of competition among medical men, and one, moreover, with which the Council had nothing to do. He suggested that the only way to tackle the matter was for medical men to form an association *ad hoc*, or to induce the British Medical Association to move in the matter. So far as the report was concerned the only point worthy of remark was that certain men undertook more work than they could efficiently perform; but he adhered to the view that this was not a matter for the Council to take up.

Mr. Wheelhouse pointed out that their legal advisers were of opinion that such associations were properly registered, whereupon, after some further discussion, Mr. Bryant asked and received permission to withdraw his motion.

Bogus Degrees.

Mr. Farrer, the Council's solicitor, reported the result of proceedings against one Steele for illegal assumption of the title of M.D., a fine of £10 having been inflicted, the sentence having been confirmed on appeal. He suggested that the Council should consider the advisability of taking proceedings against the manager of the association for granting these sham diplomas, either directly or by the Attorney-General.

After some discussion a resolution was agreed to authorising the President to take such steps as might appear advisable to put an end to the granting of so-called degrees by the "General Council of Safe Medicine."

The Certification of Midwives.

A number of communications bearing on the certification of Midwives were received and ordered to be entered upon the Minutes, whereupon,

Mr. Wheelhouse moved that "On and after January 1st, 1895, any registered medical practitioner who shall sanction the issue to any midwife or other person who has not passed a qualifying examination in medicine, surgery, and midwifery, as provided by the 'Medical Act, 1886,' of a certificate or diploma which should imply a qualification to practise midwifery, should be considered to have been guilty of infamous conduct in a professional respect." He urged that the issue of these certificates constituted an attempt to evade the provisions of the "Medical Act, 1886," and to institute an entirely new class of practitioners. He displayed a selection of such certificates to show how closely they resembled diplomas, and he pointed out that the resemblance was such as to mislead the public. He concluded by an appeal to the Council to show that they were in earnest in the matter, and to lay it down that none but fully qualified persons should be authorised to practice midwifery.

Sir Dyce Duckworth seconded the motion.

Dr. MacAlister contended that as the Council had no power to prevent unqualified persons practising medicine it was absurd to pretend that they could stamp as infamous conduct the giving of a testimonial by any one person to any other. The certificates complained of had no legal status, but were only testimonials of ability to do a certain thing. He could not see any distinction between the giving of these certificates and the testimonials which he himself might give to a house-surgeon or house-physician. It would be absurd for the Council to declare that a woman could not help another woman in labour unless she were fully qualified. Such certificates at any rate secured a modicum of technical knowledge on the part of these women, and this, he maintained, was a thing to be encouraged. He maintained that the Council could not thus condemn unheard a whole class of men.

Dr. Atthill said what they ought to aim at was to prevent the giving of illegal certificates such as the M.D. (Bc) referred to previously. He said he would like to see these women educated, but he protested against anything implying their registration.

Sir Walter Foster pointed out that they could not prevent women acting as midwives, but he thought it would be well if they could check the giving of certificates which so perilously resembled diplomas. He thought, too, that a caution should be given to institutions officered by medical men as to the kind of certificates allowed to be issued.

The President suggested that the better plan would be to summon one or two of the officers before the Council to answer a charge of infamous conduct in the granting of these certificates. General declarations were useless and impracticable.

Mr. Carter then brought forward an amendment to the effect that the issuing of any document bearing a colourable resemblance in appearance or phraseology to a diploma would render the donor liable to be visited with the condemnation of the Council, winding up with a request to the President to repeat the warning already given in this respect.

Sir **William Turner** seconded the amendment, which gave rise to a discussion, but was ultimately agreed to unanimously.

Reinstatement.

A report was brought up from the Executive Committee on the request of Mr. E. B. de Robertson to be restored to the *Register*, and after the usual deliberation *in camera* the name was ordered to be restored, in accordance with the report.

The Council then adjourned.

SECOND DAY.—Wednesday, May 23rd.

After a graceful tribute of respect and esteem to Sir James and Lady Paget on the occasion of their golden wedding, the Council proceeded to the consideration of the penal cases.

The first on the list was the case of George Davidson, M.B., M.Ch., Glasgow, who was summoned before the Council on a charge of "covering" an unqualified black person named Mylan at Sheffield. This was a case that had been adjourned from the November session, and the charge was laid by the Medical Defence Union.

Various affidavits were read in support of the charge, and Dr. Davidson was examined in his own defence. He admitted that his salary was paid by Mylan, though he claimed that he was the principal and Mylan merely his assistant. After the usual deliberation *in camerâ*, Mr. Davidson was recalled and the President informed him that he had been adjudged guilty of the charge, and that his name had been ordered to be removed from the *Register.*

Case of John Melvin Campbell.

Mr. Campbell, who is registered as L.S.A., London, was charged with being associated with a firm in Queensland for the purpose of aiding the sale of quack medicines and otherwise enabling them to carry on a medical practice which is objectionable and dangerous to the public. The complaint was laid by the Queensland Medical Board.

Evidence was given by affidavits in support of the charge, and certain advertisements were produced in which the defendant was styled the "Medical Referee."

The defendant, who did not appear in person, had sent in a defence which was read, in which he claimed that the institute in question, known as "The Progressive Remedy Institute," was conducted on strictly legal and legitimate principles.

As the defence was virtually an admission of the charge it did not take much deliberation *in camerâ* for the Council to decide to order Mr. Campbell's name to be removed from the *Register.*

The Case of Eliza Frickhart.

This case was brought to the notice of the Council at their last session, when cognisance was taken of the withdrawal of her diploma by the Royal College of Physicians of Ireland for advertising, in contravention of her undertaking not so to do. She, however, still remained on the *Register* in virtue of the additional qualification of M.D. Zurich. She was now summoned to appear on a charge of infamous conduct in this matter of advertising, and after formal evidence had been alleged of the offence, the defendant neither appearing nor entering any defence, the Council ordered her name to be erased from the *Register.* Mrs. Frickhart thus enjoys the proud distinction of being the first woman not to be entered upon, but to be removed from, the *Register.*

Case of Denis Collins.

The next case was that of Mr. C. Denis Collins, M.R.C.S.E., who was arraigned on a charge of "covering" an unqualified person at Liverpool, and of assisting in advertising certain quack remedies, and of "seeking to attract medical practice and induce foolish and credulous persons to consult him by circulating improper and discreditable advertisements and pamphlets." The defendant did not appear to defend himself, and the case was described as "one of the worst that had ever been brought before the Council." The principal affidavit was one by Inspector Robertson, of the Liverpool Constabulary, who had been concerned in bringing the defendant's associate to justice, he having been sentenced to five years' penal servitude for cruel frauds on poor people.

After a brief deliberation the Council ordered his name to be erased from the *Register.*

Case of Neville Holland.

Mr. Neville Holland is also an M.R.C.S., L.S.A., and was charged with issuing a false certificate of death and acting as cover to one Davies in Bethnal Green.

This case was brought forward by the London and Counties Medical Protection Society. Evidence was produced of the conviction in respect of this certificate.

The defendant denied the covering, admitting only a single act of impropriety in the giving of this certificate, adding that he always saw patients who were in a dangerous condition or who required more skilled attendance than his unqualified assistant could give.

This, however, was practically no defence at all, and the Council after due deliberation ordered his name to be removed from the *Register.*

The Council then adjourned.

THIRD DAY.—Thursday, May 24th.

The Council again took up the consideration of the penal cases, of which there was such a rich supply, the next defendant being Mr. Stephen Berry Niblett, L.S.A., L.R.C.P.Ed., L.F.P.S.Glasg., of Adlington, Lancashire.

The charge was made by Mr. W. H. Murray, and, as formulated by the Council's solicitor, it ran, that the defendant had sought to attract practice by a method of publicly advertising his name, address, and qualifications, suggesting to persons to consult him, and inviting them to purchase his cures, remedies, and medicines, in a form which is professionally discreditable.

Mr. Niblett appeared in person, but could not very well explain away the damning advertisements. *Litera scripta manet*, and the Council saw no course open to them but to order his name to be erased from the *Register.*

The Case of Alexander Nairne.

The charge against Mr. Alexander Nairne was that of covering one Currie, who is running a so-called drink-cure at an establishment which rejoices in the name of the "Metabolic Institute" at Glasgow.

Mr. Nairne appeared in person, and without seeking to justify his association with Currie he intimated that he had definitely severed his connection with the institute, and promised never again to allow himself to be drawn into such a compromising association.

Thereupon the Council came to the conclusion that while Mr. Nairne's conduct was of the nature of a "serious indiscretion" they had decided not to declare it to be "infamous conduct in a professional respect," so they just cautioned him in future to be more circumspect.

Case of Mr. Robert Ingram Robertson.

Mr. Robert Ingram Robertson, M.B., M.Ch.Glasgow, was charged at the instance of the Medical Defence Union with covering one Graves, at Penarth. A letter was read from the defendant explaining his non-appearance on the ground of illness, so the consideration of the case was postponed until Saturday, an intimation being ordered to be conveyed to the defendant to the effect that a medical certificate would be necessary in regard to his inability to attend.

Mr. E. W. Alabone Redivivus.

A correspondence was laid before the Council between Mr. E. W. Alabone, whose name was erased from the *Register* many years ago for advertising. The correspondence comprised a letter from Mr. Alabone's cousin, a solicitor, in which it was contended that Mr. Alabone's name had been erased from the *Register* without due deliberation, merely on the ground that his diploma of M.R.C.S. had been withdrawn by the College of Surgeons, and that in accordance with the judgment in the case of Partridge v. the Council it was incumbent on the Council forthwith to restore his name to the *Register* pending a proper inquiry into the charges.

A reply has been sent from the Council pointing out that the Partridge judgment was under the "Dentists' Act," which differed in various points from the "Medical Act" under which the Council had acted.

These and other letters were submitted to the Council, and the matter was discussed *in camerâ*. On strangers being readmitted the Registrar was directed to reply to Mr. Alabone's solicitor "That the Council declines to restore his name to the *Register* or to hold any inquiry into his conduct."

CASE OF DR. HERBERT TIBBITS.

A communication from the R.C.P.Ed. was read announcing that Dr. Herbert Tibbits had been deprived of his Fellowship and Membership for "infamous cnduct in a professional respect."

The Council then took cognisance of a communication from Dr. Tibbits protesting against the removal of some of his qualifications from the *Register* on the ground that such removal was illegal, the qualifications erased having, as he alleges, been withdrawn from him because he had adopted the theory of the beneficial treatment of disease by currents of electricity of small power, a theory of medicine, hence "the erasure is as much illegal as if a homœopath were deprived, and more so." The letter was dated from "The Massage Hospital," Weymouth Street, W. Of course, as a matter of fact, the Council has no option but to order the erasure from the *Register* of diplomas that have been cancelled or withdrawn, and a reply was therefore ordered to be sent to Dr. Tibbits the Indignant, to the effect that his letter had been considered, but that the Council declined to hear him on the question of the removal of the qualifications in question.

The next step was a resolution directing that an inquiry be made at the next session of the Council into Dr. Tibbit's conduct.

A QUESTION OF PUPILAGE.

Dr. **TUKE** called attention to the registration of six students as pupils of a certain registered practitioner who is said to be a science master in the public day school whereat these students are ordinary day pupils, such day school having been recognised by one of the licensing bodies as a teaching institution where the subjects of physics, chemistry, and biology are taught. The matter was referred to the Education Committee for consideration and report next session.

THE REGISTRATION OF STUDENTS IN ARTS OF THE UNIVERSITY OF DUBLIN AS MEDICAL STUDENTS.

Dr. **HAUGHTON** moved that the Registrar of the Branch Council for Ireland be instructed to enter in the Register of Students the names of students in Arts of the University of Dublin furnished to him by the official list of each year under four headings. The matter had been considered by the Education Committee, who recommended that the request be acceded to, and their report was agreed to and adopted.

The Council then adjourned.

FOURTH DAY—FRIDAY, MAY 25TH.

The first business te come up for consideration was the already much debated subject of the Report of the Education Committee on Section 5 of the Draft Ordinances, Edinburgh, No. 10, issued by the Commissioners acting under the Universities (Scotland) Act, 1889.

It is hardly necessary to recapitulate these very technical details. Suffice it to say that the explanations of the Commissioners are not regarded as satisfactory by the Council, and on the motion of Dr. **MACALISTER**, it was resolved that a copy of the report be sent to the Scottish Universities Commission, it being at the same time pointed out:—

"(1) That Clause V of the Draft Ordinance, supplementary to Ordinance No. 14, does not meet the objections against Section X, which have already been urged by the General Medical Council, inasmuch as it does not require that a candidate on whose behalf special grounds are alleged shall have passed a Preliminary Examination in Arts or in Science before commencing the study of the special subjects of the first *annus medicus*.

"(2) That in the preamble to the Draft Ordinance, no reference is made to the fact that, in the opinion of the Commission, it is desirable to limit the powers given by Section X.

"(3) That in the interest of medical education in general, and of the medical departments of the Scottish Universities in particular, it is desirable that the action of Section X should by Supplementary Ordinance be suspended."

On the motion of Dr. **TUKE**, it was agreed:—

"(1) That the President be further requested to communicate with the Lord President of the Privy Council, asking that in case an Ordinance supplementary to or otherwise dealing with Section X should be submitted by the Commissioners for Her Majesty's approval, the General Medical Council may through its President be notified of the fact, and have an opportunity of representing to the Committee of the Privy Council its views thereupon.

"(2) That, if necessary, the President be authorised to take the necessary steps for presenting the views of the Council before the Committee of the Privy Council."

DEFICIENT PRELIMINARY EDUCATION.

The Council decided to adopt the report by the Education Committee on deficient preliminary education. This report states that the returns from English and Scottish bodies are satisfactory so far as the numbers given therein are concerned, and the Council is congratulated (by its Committee!) on the effect of their action in the matter. Attention is called to the fact that no return has been made by any of the Universities or by the Society of Apothecaries of London. The Irish returns are less satisfactory, and special attention is called to the fact that out of 19 instances of bad spelling, 13 were those of candidates who had passed the preliminary examination of the Royal College of Surgeons of Ireland. This, by the way, is one of the preliminary examinations to which, in the Council's list, a note is now appended stating that "the Council has recommended that these examinations be discontinued." The returns, as they stand, support the opinion expressed by the Committee in previous reports, that it would be for the public good were all preliminary examinations in general education handed over to purely educational bodies.

THE SOCIETY OF APOTHECARIES OF LONDON.

The report of the Examination Committee on the qualifying examination of the Apothecaries' Society of London was then presented and adopted. There is nothing of much interest in this report, which states that the final examination is "sufficient," albeit the scope of the clinical parts was not as comprehensive as that of some other licensing corporations. The examinations in pathology, urine-testing, medical jurisprudence, and ophthalmology were the subject of special commendation.

THE ROYAL COLLEGES IN IRELAND.

The next item was the report of the Examination Committee on the final examinations of the Conjoint Examining Board of the Royal Colleges in Ireland. This report expresses satisfaction that an attempt has been made to comply with the Council's recommendations, though various criticisms and suggestions are still thought necessary in respect of the *technique* of the examinations. The report was adopted after a desultory discussion.

Various odd matters then came up for discussion. Steps were ordered to be taken, on the initiative of Dr. **MCVAIL**, to establish a mode of procedure when persons whose names have been removed from the *Register* for infamous conduct apply for reinstatement. Another motion was agreed to, on the proposal of Dr. **GLOVER**, referring it to the Executive Committee to ascertain what means would be adopted to stop the practice of persons continuing to use titles attached to the diplomas of which they had been deprived and which no longer appeared on the *Register*.

On the motion of Dr. **MACALISTER** it was agreed to refer to the same committee the question of acting on the proposals emanating from the British Medical Association.

Lastly, it was resolved that the Registrar be instructed to publish annually, in a prominent place in the medical journals, the resolutions of the Council in respect of the offence of "covering," and to supply a copy of the Regulations to every person applying for registration.

The Reports of the Pharmacopœia and Finance Committees were received and entered upon the Minutes, as were also sundry other documents and returns.

FIFTH DAY—SATURDAY, MAY 26TH.

After some formal business the Council proceeded to hear the evidence in

THE CASE OF ROBERT INGRAM ROBERTSON, M.B. ED.,

whose case was adjourned from Thursday. Mr. Robertson was charged with covering one, Graves, at Penarth, and did not put in an appearance, sending instead a medical certificate to the effect that he was ill. As, however, the evidence was principally documentary, the Council resolved to proceed in the matter, and after listening to a written defence, the defendant was adjudged guilty of the charge and his name was ordered to be removed from the *Register*. This case was taken up at the instance of the Medical Defence Union.

In re the L.D.S.R.C.S.I.

A report was brought up from the Education Committee in respect of the licence in dentistry of the Royal College of Surgeons in Ireland.

The Committee are of opinion that, in consequence of the Royal College of Surgeons in Ireland not requiring from candidates evidence that they have received instruction in mechanical dentistry during three years from a registered dental practitioner, the course of study prescribed by the said College is not such as to secure the possession by persons obtaining the licence of that college of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery; and they recommend the Council to represent this opinion to the Privy Council, and to request the Privy Council to make order that the certificates granted under their present regulations by the Royal College of Surgeons in Ireland shall not confer the right to be registered under the *Dentists Act*.

The Committee are further of opinion that candidates for the said licence who hold a diploma in surgery, and who, by the regulations of said College, "are only required to produce certificates of one year's attendance at a dental hospital, where such attendance has been subsequent to the date of diploma" (*see* "Exemptions," Appendix C), should not be admitted to the examination for the licence.

The Committee are of opinion that the time has come for putting into force the powers conferred by section 22 of the *Dentists Act* for the visitation and inspection of the examinations held by the bodies conferring dental qualifications.

On the report being brought up for adoption by Dr Tuke,

Sir Phillip Smyly said the President of the College of Surgeons had assured him that every endeavour would be made to fall in with the views of the Council. He moved as an amendment that the actual threat should be omitted, seeing that it was the intention of the College to conform to the wishes of the Council.

Dr. Haughton, as a member of the committee, said he did not think after what had fallen from the last speaker that it was necessary to press the matter.

Dr. Tuke observed that the President's assurance was not enough and he urged on the Council to support those members of the Council of the College who were desirous of conforming.

Dr. MacAlister pointed out that there was said to be a difference of opinion on the Council of the College, and he suggested that the resolution would afford an irrefutable argument to strengthen the hands of those who were disposed to do what was demanded.

After a desultory discussion, Sir Philip Smyly withdrew his amendment, whereupon the recommendation of the committee was adopted *nem. con.*

On the proposal to visit and inspect the examinations it was pointed out by Sir Dyce Duckworth that there were no funds available for the purpose, and the proposal was consequently allowed to fall through.

The Conjoint Board of the Royal College of Surgeons, Ireland, and the Apothecaries Hall, Dublin.

A very important report was brought up by the Examination Committee in respect of the Conjoint Board of the College of Surgeons in Ireland, and the Apothecaries Hall of Dublin.

The complaint was laid by the Royal College of Physicians of Ireland, and it was alleged that licenses to practice had been granted to candidates who had never been called upon to pass any examination in physiology or chemistry. Various other criticisms were made, and the Examination Committee, having inquired into the matter, recommended that, having regard to the laxity and incompleteness of the examinations of that Board, as proved by the two recent inspections of them, the continuance of that combination in Dublin is no longer desirable, especially when the small number of students who avail themselves of it is considered, adding that the Royal College of Surgeons "would be well advised to sever its connection with the Apothecaries' Hall."

Dr. MacAlister did not think the Council was entitled to suggest that the College should sever its connection with the Hall. The proper course was to inspect the examinations to see whether the standard was being raised.

The Council went into committee to consider the report.

Dr. MacAlister pointed out that if the report were adopted the Council would be bound under its statutes to report the matter to the Privy Council.

Sir Walter Foster thought that such a course would be unduly harsh.

Sir W. Dyce Duckworth said the attention of the College had already been called to the matter without effect.

Sir Phillip Smyly said that on receipt of the report the examiners in medicine had resigned, and two examiners had been appointed in their place. Under these circumstances he thought the wholesale condemnation was not called for.

Dr. Moore (representing the Apothecaries Hall) assured the Council that it was the earnest wish of the Hall authorities to conform to any suggestion on the part of the Council. He discussed some of the items of the complaint in detail, and took upon himself the blame for the non-production of specimens in the examination on forensic medicine at the last examination but one. He urged, in evidence of the esteem in which the examination was held, that a large number of Englishmen came over yearly to take the licence of the Hall "in order to appear well before the public" and he concluded by an appeal *ad misericordiam*.

Dr. Atthill pointed out that out of a total of 37 candidates during the last five years otherwise qualified in surgery, not one had been rejected. He suggested that this fact might explain how it was that they preferred the licence of the Hall to any other.

Dr. Heron Watson moved as an amendment that every examination of this Conjoint Board should be inspected and reported upon for the ensuing twelve months.

Mr. Carter urged that in view of the report the Council was in duty bound to take the course suggested by the Committee.

Mr. Teale pointed out that at the last examination all the candidates were rejected in medicine, a fact which he took to be a sign of grace.

Sir Dyce Duckworth said the view of the committee was that the Conjoint Board had shown itself hopelessly incompetent to discharge its duties, and he warned the Council that sympathy was wasted on the Board to the detriment of the public, who suffered at the hands of incompetent practitioners.

Sir Walter Foster pointed out that not a single offender under the penal clauses had held the licence of the Dublin Hall.

The discussion was ultimately adjourned until Monday.

SIXTH DAY—Monday, May 28th.

The Council resumed the discussion on the report of the Examination Committee on the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries Hall, Dublin. The motion before the Council was the recommendation of its committee that the deficiency should be reported to the Privy Council.

After some animated discussion, however, the Council adopted an amendment standing in the name of Dr. Heron Watson, according to which the milder course of inspecting and reporting on each examination for the next twelve months will be adopted.

We shall give the full report of the Monday's procedings in our next issue.

The Freemasons of Chicago have established a hospital for the special benefit of members of the fraternity in that city.

The Operating Theatres.

ST. MARY'S HOSPITAL.

Volvulus of the Sigmoid Flexure.—Mr. **Norton** operated on a man, æt. 55, who had been admitted to the hospital for acute obstruction of the bowel. The patient stated that for some months he had been suffering from constipation, the motions being passed in small nodules. Eight days previous to admission the bowels had ceased to act altogether, nor had any flatus been passed, but some watery discharge had on two or three occasions escaped from the rectum. The abdomen was distended and felt very tense, and it was somewhat difficult to decide whether or not the descending colon was likewise distended. Examination by the rectum showed no sign of fæcal matter, the rectum refused also to retain any quantity of fluid injection. It was diagnosed that the obstruction was in the sigmoid flexure, and, as the history pointed to the fact that there had been persistent chronic constipation, terminating suddenly in acute and complete obstruction, it was anticipated that the cause of obstruction would be found to be malignant contraction of the sigmoid flexure, and it was decided that no time should be lost before proceeding to operation. A vertical incision was made about four inches in length on the outer side of the left rectus abdominis. On inserting the hand into the abdominal cavity the sigmoid flexure was found to be fully distended, and the lower curve of the same gut twisted upon itself, and dilated up on to the right hypochondrium. An attempt was made to draw down the distended bowel through the opening for the purpose of untwisting it, but it was found to be impossible to do this without too great risk of rupturing the bowel. The incision was therefore extended across the rectus; even now the bowel could not be withdrawn, and it was found necessary to puncture it to allow the escape of the flatus. The punctured wound after having served its purpose was united by Lembert's sutures. The bowel was next withdrawn untwisted, returned into the abdomen in its natural position, the severed rectus united by sutures, and the abdominal wound closed in the usual manner. Mr. Norton remarked on the extreme tension of the bowel and the great length of incision which was unavoidably necessitated. He drew attention to the fact of his having been obliged to puncture the bowel for the escape of the flatus, and to the subsequent complete closure of the puncture, the making of which, he considered had added little or no extra risk to the operation.

ST. BARTHOLOMEW'S HOSPITAL.

Ovariotomy.—In the admirably-appointed theatre attached to the Martha Ward, Mr. **Harrison Cripps** removed a very large ovarian cyst from a woman, æt. 28. He said that it had increased rapidly in size, especially of late; some idea of its extent may be gathered from the fact that the patient measured 60 inches round the waist. There had been some idea that the fluid might merely be ascitic. On cutting down, the walls of the tumour were found to be so adherent to the parietal peritoneum that the incision into the latter opened the former; the cyst was also adherent to the omentum and to the transverse colon. Some little difficulty was experienced in breaking down these adhesions; the handle of the knife and the finger nail were used for this purpose. The abdominal incision had to be several times extended. When the cyst was brought out of the abdomen the pedicle, which was found to be very broad, was tied with four ligatures; it was then cut through and the tumour removed. The abdomen was next thoroughly flushed out with tepid water, all hæmorrhage arrested (mostly by ligature, but Paquelin's cautery was applied to two or three oozing points), part of the omentum ligatured and cut off, and the wound closed by one row of sutures, each suture including the whole thickness of the abdominal wall and also the peritoneum, a glass drainage tube being left in. The tumour contained about 44 ounces of fluid and many secondary cysts with papillomatous growths. Mr. Cripps pointed out that these growths would be regarded as malignant if found without a capsule in a breast, for instance; in the case under consideration he said they were benign, as they were so completely encysted. He said the main features in the operation he had just done were the large size of the tumour, its close adhesion to the parietal peritoneum, and the extreme breadth of the pedicle, which necessitated the employment of four ligatures instead of two.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 30, 1894.

THE GENERAL MEDICAL COUNCIL.

Foremost among the subjects which have engaged the attention of the Council during a busy session was the burning question of the Medical Aid Associations. It came before the Council on a motion by Mr. Bryant, who asked the Council to direct an inquiry to be made as to whether these associations, conducted by laymen for profit, were rightly registered under the "Friendly Societies Act (1875)," pointing out at the same time that medical practice under such circumstances was degrading to the medical profession and injurious to the public. There was no serious difference of opinion as to the derogatory nature of this modern form of medical "sweating"; but Dr. Wilks and others thought fit to repeat what they have said before as to its being no part of the duty of the Council to intervene in a matter which, according to this gentleman, is only a question of competition between local practitioners. This particular motion fell through because the legal advisers of the Council declare these associations to be rightly registered under the Friendly Societies Act; but the matter will certainly come up again in some other form. It is undoubtedly a very grave matter from a professional point of view, and the Council cannot be allowed to go on shelving the problem indefinitely. The simplest way would be for the Council once and for all to declare that holding office under such circumstances is "infamous conduct in a professional respect," ignoring Dr. Wilks's contention that the Council exists not for the benefit of the profession but solely to protect the public. We must leave it to the legal advisers of the Council to frame a resolution which shall attain the object which we have in view without interfering with the holding of other perfectly admissible paid offices under trading companies, such, for example, as that of referee to life assurance companies and the like. The object is to prevent medical men becoming the paid servants of a body of laymen who, under the specious guise of charity, provide medical attendance for ridiculously inadequate payments, quite irrespective of the subscribers' social and financial status, employing means, moreover, to obtain adherents which would expose any medical man guilty thereof to erasure of his name from the *Register* On the strength of the contention put forward by Dr. Wilks, the Council, until the last few years, consistently and persistently refused to put down "covering," and enough of the old spirit of *laisser faire* still permeates this body to prevent anything useful being done to prevent the illegal assumption of titles and the illegal practice of medicine generally. We contend, as we have always contended, that the functions of the Council are twofold, towards the public and towards the profession. The number of penal cases this session was unusually large, and in every instance but one the name of the offender was ordered to be struck off the *Register* An excellent departure has been resolved upon in order the better to check the still rampant practice of "covering," viz., that once a year the regulations of the Council in this respect shall be accorded a prominent place in the medical journals, and a copy thereof is to be handed to everyone applying to be registered. Steps are also to be taken to prevent persons who have been struck off the *Register* making use of titles derived from diplomas which they no longer possess the legal right to claim, and a modification of the existing Standing Order was agreed to whereby it will be in the power of the Council virtually to defer sentence, thus giving the offender a chance of retrieving his position by exemplary conduct during a period of probation. Among the other matters which engaged the attention of the Council were two concerning the Royal College of Surgeons of Ireland, which was made to appear in a very unenviable light. According to the report of the Education Committee, the omission from the schedule of requirements of that body applying to candidates for the dental licence of any provision for a period of practical instruction "fails to ensure a proper standard of proficiency." The Council, therefore, resolved to report the matter to the Privy Council. The College again appeared as defendant in respect of the shortcomings of the Conjoint Board with the Apothecaries Hall of Dublin, the examinations of which Board are reported to be ridiculously inadequate. We must confess to a difficulty in understanding the attitude of certain members of the Council in endeavouring to procrastinate in such a matter. Obviously, as soon as the damning report is adopted, the Council has really no option under its statutory powers but to intimate the deficiency to the Privy Council, and we see no reason why such a course should not be taken directly it becomes apparent that a first intimation to the peccant Board has not been complied with. The Council, however, decided not to push matters to this logical issue, and adopted instead a motion providing for the closer inspection of the examinations of the Conjoint Board during the ensuing twelve months.

◆

THE LAW OF CREMATION.

An interesting book has been published by Mr. Aubrey Richardson, of Lincoln's Inn, dealing with the law of cremation, ancient and modern. It contains an immense amount of information, gathered from many sources, and is a noteworthy contribution to the subject. The first part discusses ancient law. Mr. Richardson concludes that the custom of cremation had its origin among the primitive Aryans, whose place of abode he fixes in Northern Europe. From that prehistoric race the crematory process spread until it influenced all the great nations of the globe except the Egyptian, the Persian, and the Chinese. Of these three races Max Müller supposes that in early times the Persians actually adopted the practice; certainly at one period it was partially accepted by the Chinese, while Monsieur Bonneau shrewdly surmises that the scarcity of wood may have had something to do with the staunch adherence of the Egyptians to their custom of embalming. The second part of Mr. Richardson's book deals with the modern law of cremation as regards foreign countries, with its difficulties, and the way in which they have been more or less successfully overcome. The writer, in introducing this section, sums up the history of the prolonged but steadily progressive nature of the conflict in the following passage: — "A survey of the various struggles in which the present-day advocates of cremation have already taken part, and in which many of them are still engaged, affords clear evidence that religious scruples are not the only obstacles in the way of the universal re-adoption of the practice of the disposing of the dead by burning. In all countries legal difficulties have had to be faced." In Frankfort-on-the-Maine and in all countries within Prussian jurisdiction cremation is forbidden. In Holland the practice, although not forbidden by law, is in abeyance. In Austria it is permitted if expressly desired in the will of testator. In Italy the dispute as to the burning of Garibaldi's body ended in the passing of the New Italian Burial Law, which granted to a testator the absolute right to determine whether his body should be burned or buried. A similar law prevails in France, where the desirability of the re-introduction of cremation into civilised society was first publicly discussed in 1797. In that country the struggle has been carried to a successful issue against all the opposition of popular prejudice and of official hostility. At the beginning of this century Comte Frochot, Prefect of the Paris Police, authorised a citizen to cremate her child. The question was allowed to drop out of sight, however, until it was again brought to the front during the Franco-Prussian war. After the battles of Wörth and Sedan the French Government resolved to incinerate a great number of corpses by a chemical process. The subject of cremation was thus again forced upon the notice of the public, and became the central point of conferences, *brochures*, commissions, trials, and official correspondence. Notwithstanding all this energy, it was not until 1887 that the Chamber of Deputies passed into law the proposition that all persons in a position to dispose of their worldly belongings by will should have complete option in regard to the burial or burning of their own bodies. This right is surrounded by various carefully-arranged safeguards, and, as is usual in France, the prices to be charged are placed within certain defined limitations, as will be seen from the following passage:—"The Municipality has, moreover, fixed 50 francs as the uniform tax to be charged, apart from the price of the urn and all decorative expenses, which vary from 12 to 200 francs, according to the class of funeral decided upon. This tax includes a right to the possession of a niche in the municipal columbarium for five years, but is only exacted from those who are in a position to pay. For the indigent, everything, including the medical certificate, is free." In Denmark the conditions of cremation are:—"The existence of a testamentary disposition in valid form, and of a sufficient legacy to defray the cost of cremation; the production of certificates obtained from the medical officer and from the police authorities setting forth the undoubted cause of death; and the depositing of the ashes in a churchyard or an officially approved crematorium." Cremation is now, more or less, extensively practised in Great Britain, Sweden, Switzerland, the United States, and other countries. The English Cremation Society is prepared to undertake the necessary incineration at Woking at a cost of six guineas, which does not include, of course, the undertaker's charge for conveying a body to their crematorium. The battle of the cremationists, therefore, may now be regarded as won, although, probably, many years will elapse before public sentiment is thoroughly educated to the value of their doctrines. Without doubt, the ancient practice which they advocate is founded on sound sanitary principles. The writer of the "Law of Cremation" has made a valuable addition to the literature of the subject. His father, Sir B. W. Richardson, has long been a consistent and staunch upholder of the practical advantages of cremation.

ANTI-VIVISECTION DISHONESTY.

Last week the London Anti-Vivisection Society held their annual meeting with an audience which made up in enthusiasm what it lacked in numbers. Judging from our own experience, it would be a good thing if medical men were to attend these meetings in larger numbers, though we cannot encourage them to seek to stem the tide of obloquy and contempt which runs against the profession at such meetings. They would at once become aware of the existence of two distinct classes of anti-vivisectionists. First, those who base their condemnation of the practice on moral and ethical grounds; those, in fact, who declare that were physical salvation and pathological immunity to be gained at such a price they would not be worth having. The others content themselves with denying the usefulness of vivisection in the pursuit of knowledge, and on this occasion the latter class was feebly represented by two medical practitioners whose names we will not rescue from the obscurity in which they pass their lives outside anti-vivisection circles. Some of the speeches were decidedly inspiriting, comporting as they did, a vivid eloquence, and, as far as one could judge, a genuine enthusiasm in the cause of animals *versus* science. It is to be regretted that orators of such talent should mar their reputation for *bona fides* by making use of arguments based on the disgraceful allegations to which certain dailies have been affording the hospitality of their columns during the last two or three weeks anent "vivisection in hospitals." Clergymen in our large towns have too much to do with hospital practice to accord even a shadow of credence to such outrageous allegations, and it is positively unfair for them to seek to make capital of statements of which they are careful not to assume the responsibility. When a bishop allows himself to prognosticate that the Sunday Hospital Fund will be "damned" if allegations in which he himself does not believe are not gainsaid, it is time to protest in the name of decency and common honesty. The poor were represented as going to the hospital in fear and trembling, inferentially on account of the vivisecting proclivities of the surgeons; though, of course, there are other more prosaic reasons for this condition of mind. We mostly go in fear and trembling to the dentist when sad necessity drags us thither, but it is assuredly not because we suspect his motives to be other than strictly professional. What particularly appeared to excite the hatred and distrust of the speakers was the fact that many, if not most, vivisectors are men who do not practise the curative art—

are men, in fact, who give themselves up body and soul to the pursuit of "knowledge at any price," men who do not seek "to find a specific remedy for a specific ill," but whose only endeavour is to advance pure science. What answer is to be made to such arguments, especially when advanced by medical men? It never seems to occur to these benighted intelligences that vivisection represents the disinterested endeavour to understand the human body and its functions in health and disease, that such knowledge is of its nature difficult and uncertain in its acquisition, and in its details subject to many and conflicting interpretations until, after the corn has been winnowed from the chaff, we are enabled to deduce some law of general application.

◆

Notes on Current Topics.

Ocular Antiseptics.

M. Trousseau introduced an interesting discussion at the recent meeting of the French Society of Ophthalmology upon the subject of the use of antiseptics in eye surgery. His method of antisepticism consists, previously to operating, in washing the lids and the conjunctiva either with a one in two thousand of a sublimate solution, or with a cyanide of mercury solution (1-1,500), or with boiling water. The curious fact is recorded in his remarks that of twelve patients examined before being submitted to an extraction operation, in one only were there no pathogenic micro-organisms to be found, and that was in a man whose state of general filthiness was, if anything, more noticeable than that which is commonly displayed by hospital patients. Among the twelve patients examined, in no less than eleven pathogenic germs were discovered. In seven streptococci were found, in six the white staphylococci. Besides these, a great number of other pathogenic organisms were discovered, and among others a bacillus analogous to the bacterium coli, as well as a bacillus which seemed to be especially confined to the conjunctiva. However, despite the presence of all these forms of micro-organic life, all the operations of extraction proved to be successful. Experience showed that the best antiseptic reagent in ocular surgery was a solution of the perchloride of mercury, then the cyanide of mercury, and lastly, as a bactericide, boiling water. The observations of Trousseau would tend to show that, despite the use of antiseptics, ophthalmic surgeons have no other course than to operate upon eyes which are charged to the full with pathogenic germs. In the course of the discussion one speaker said that in his opinion the source of infection of the wound in cataract cases came from the lids and the lachrymal sac rather than from the conjunctiva. Another speaker spoke highly of the advantages of the cyanide of mercury as an ocular antiseptic, stating that it was three times less irritating than any other, while a third speaker observed that he considered it of the utmost importance to thoroughly wash the lids and surrounding parts with soap and water, and then douche them with a sublimate solution (1 in 1,000) before operating for cataract. M. Meyer summed up the discussion very tritely by saying that he did not doubt that the presence of the most virulent germs in the conjunctival sac did not necessarily prevent a successful result being obtained after an operation for cataract. Nevertheless, he considered that it would be dangerous to conclude from this fact that antiseptics and aseptic methods, which were universally used in cataract operations, could be dispensed with. These observations were well timed, inasmuch as in pre-antiseptic days the losses of eyes after cataract extraction amounted to no less than ten per cent. from suppuration.

The Certification of Midwives.

In spite of the warning addressed to the various institutions and bodies granting certificates of competency to aspirant midwives a few months since, Dr. Rentoul has found it necessary to bring the matter before the General Medical Council. This gentleman is one of those who does not know when he is beaten. Felled by a blow which would quench the ardour of other men, he appears, after a brief interval, as determined as ever. He presented his protest to the Council, on this occasion, in such form that it could not be ignored, for he printed all the sham diplomas in full, with appended facts and criticisms. We have always strongly opposed the system of granting quasi-official certificates in this or that special department of medicine by private persons or associations of persons, and there is no gainsaying the fact that the holders of such certificates do consider themselves legally licensed to practise midwifery. Although at first sight it seems an unjustifiable interference with the liberty of the registered subject to prohibit him or them giving certificates to students after a course of training, there are valid reasons for discouraging their issue by irresponsible persons. The Council has now declared that the giving of certificates, which, in appearance of phraseology, resemble diplomas conferring a right to be registered as a medical practitioner, is a proceeding which "will be liable to be visited with the condemnation of the Council." This somewhat vaguely-worded intimation may or may not have the desired effect. The principle on which it is based is strictly comparable to the law which forbids the issue of colourable imitations of bank notes or postage stamps; but it will be a delicate task to decide in any particular instance whether or not the incriminated document falls within the limit of the condemnation. We should be sorry to see half-a-dozen of the most prominent members of the Obstetrical Society of London declared to be worthy of censure and erasure; but until an example has been made this remunerative practice is likely, in a more or less attenuated form, to persist. The great argument against interference is that the law does not prohibit one woman assisting another in labour, however little she may know of the process, and one effect of the possibility of obtaining a certificate of competency is that it acts as a stimulus to go through a course of training. Imperfect as such training may be, it is always so much to the good. It is, however, obvious enough that, strictly speaking, there is no analogy between a woman that helps a suffering sister in love, and one who lends her services for gain.

Experiments in Compressed Air Pathology.

An interesting report has recently been submitted to the London County Council bearing on the health of the men engaged in driving the tunnel under the Thames below London Bridge. The total number of men engaged in the work is 120, all of whom have to work at an air pressure of twenty pounds to the inch above atmospheric pressure. They are on eight hours' shifts except the two foremen, who are on duty for ten hours. So far only six of this number have complained of illness, a very small proportion, especially as there is nothing to show that their indisposition had anything to do with the peculiar conditions under which they work. Special precautions are taken to avert the disastrous consequences which are apt to attend too rapid a transition from this high pressure to the normal. The men are ordered to remain three minutes in the "air-lock" which separates them from the exit portion of the tunnel; but it is stated that the greatest difficulty is experienced in inducing the men to comply with the regulations in this respect owing to their anxiety to get away once their allotted task has been completed. Such impatience is perfectly natural; but we trust the orders will not require to be reinforced by the spectacle of several of their number succumbing forthwith to the apoplectic results of "caisson disease." The men are all subjected to a medical examination before being taken on in the tunnel works, and it was evidently to be desired that this examination should be made periodical in order to ascertain whether this working under pressure really determines any notable deterioration of the general health. Arrangements have now been made for this to be done by a local practitioner, and a careful record will be kept of the symptoms and incidence of maladies affecting these particular workers. The treatment of certain lung affections by compressed air has obtained some vogue, and it has been suggested that sufferers might get an economical course of treatment by passing a few hours daily in the workings, the proceeds to be devoted to the reduction of the capital cost of the undertaking.

Strychnine as a Narcotic Antidote.

Dr. Washburn (*Therapeutic Gazette*) reports the successful use of strychnine in a case of chloroform narcosis. The patient confessed that he had swallowed two ounces of Squibbs' chloroform with suicidal intent. When seen the patient was in a state of coma. "His eyes were upturned, and the dilated pupils did not react to light; his respirations were exceedingly shallow, irregular, and scarcely perceptible, and he had the weak, uncertain, irregular pulse of a dying man." Treatment was commenced by the hypodermic injection of 1-20th gr. of strychnine, and then for a short time artificial respiration was practised. Within a few minutes there was a remarkable change in the whole aspect of the case, not only in the appearance of his countenance, but in the character of his pulse and respiration. "The respirations soon became so deep, regular, and vigorous that I was enabled to reach the conclusion that the man was suffering from chloroform narcosis, the odour of his breath indicating what he had swallowed. One subsequent injection of 1-60th of a grain of strychnine was given about an hour after the first"; and an hour afterwards the patient told of his attempted suicide. The therapeutic antagonism of chloroform and strychnine has not been sufficiently impressed on the medical mind. It is true that in cases of strychnine poisoning chloroform is quickly and freely resorted to; but in chloroform narcosis we seldom read of the hypodermic use of strychnine. To this neglect of a very powerful drug, the properties of which are well known, and the antidotal value of which in chloroform poisoning has been recognised, may be ascribed the loss of many lives. In 1880, Dr. Nicholson proved its value in chloroform narcosis (*South. M. Rec.*, vol. x); and amongst the antidotes to chloroform and ether narcosis strychnine is included in "Anæsthetics, Ancient and Modern."

Experimental Anæsthesia at Sea.

An anxious experience of the anæsthetic action of the vapour of paraffin is reported to have occurred on board the oil tank steamship *Kasbek* while on her voyage from Batoum to London freighted with paraffin oil. A leakage was discovered, which was found to be seriously on the increase. At length it became necessary to put a stop to the leak, but this was attended with no ordinary danger, as the hold was now full of an explosive vapour, and could not be approached by artificial light. Subsequently this difficulty was overcome by throwing the reflected daylight by the aid of a mirror into the hold. By this means the position of the leakage was discovered, but the men could not remain long enough to repair the same in consequence of the asphyxiating effect of the accumulated gaseous vapour. Ropes were now made fast round the bodies of the more adventurous of the crew, and when they were no longer able to proceed with their work they were quickly hauled up. Some of them on reaching the fresh air appeared to be in a state of intoxication, while others were in a laughing or crying mood. The captain had himself lowered, not only to determine the extent of the leakage, but to ascertain the condition of things. He was down but a very few minutes when he was drawn up to the deck in an unconscious condition, from which he did not perfectly recover for several hours. At first sight it will appear that the breathing of the accumulated vapour of paraffin resembled that of nitrous oxide gas.

The Proposed New Order of Midwifery Practitioners.

We are glad to see that Dr. Rentoul's determined advocacy of the cause of those who are opposing legislation for the registration of midwives is being well-seconded by the large and important branch of the British Medical Association to which he belongs, A short time ago, a committee of the branch in question – the Lancashire and Cheshire—was appointed "to draw up, to watch the progress of, and to oppose any proposed legislation for the registration of midwives." On the 11th inst., the branch had a special meeting for the purpose of receiving the report of its committee upon this question, and it is satisfactory to be able to record that the report in its entirety was adopted. Among other matters agreed to, was the suggestion to place at the disposal of the committee a sum of money not exceeding £250, to be taken out of the reserve fund of the branch, so as to enable the committee to carry on the work for which it had been appointed, the details of which are set forth in its report. The last clause contained therein should be noted by medical men generally :—"That a copy of your committee's report be forwarded forthwith by the honorary secretary of this branch to the Council and the Parliamentary Bills Committee of our Association, to each of the home branches, and to each medical society, asking each of the branches and societies to appoint a committee, and to vote a sum of money, so that each committee may oppose any proposed legislation for the so-called Registration of Midwives." If this plan were duly carried out as suggested, the opposition could not fail to be so powerful as to dispose very effectually of the promoters' scheme of registration.

Good News for Surgeons.

In the report of a case of Undescended Ovary in last week's "Operating Theatres" there is a statement which must indeed come as good news to all operating surgeons. After the removal of the undescended ovary, "the opportunity was taken to examine the left kidney, which, a year before, had been explored and its cortex incised by the same surgeon for suspected calculus. It was now found to be perfectly healthy, showing that the previous operation had produced no deleterious effect on that organ." This, undoubtedly, is most satisfactory. Of course, all surgeons are well aware by experience that exploration of a kidney for stone (when the organ may practically be regarded as healthy so far as its own structure is concerned) not only gives rise to no bad consequences, but even in many cases puts an end to all symptoms and absolutely cures the patient, yet it must be excessively rare for the operator to have the opportunity of examining and handling (through an opening in the abdomen made in order to deal with quite a different organ) a kidney which he has incised and explored a year previously. The positive experience of the case in point is certainly of more value than the mere negative result of no harm having accrued in many cases of exploration of the kidney, for the pessimist could perhaps say that the healthy urine given in proof in the latter instance might be secreted by the other kidney, and that the one operated on was atrophied and reduced to inactivity.

A New Fraud upon Medical Men.

To write a certificate with the colourable imitation of a medical man's name and qualifications for the purpose of enabling a person to evade the course of justice appears to be the newest device for fraudulently bringing discredit upon the profession. The facts of a case of the kind have recently been reported by the *Devon and Exeter Gazette.* A judgment summons had been issued against the creditor of a brewery company at a local county court. But when the case came on for trial, a letter was handed to the county court judge intimating that the defendant had gone to Bath, that his health was most critical, and that it was impossible for him to attend. The document was signed Lewes King, "M.N.G.S." The judge not feeling satisfied, however, with the authenticity of the signature, consulted the "Medical Directory," and afterwards he said that there was no such name on the list. It was clearly, therefore, a deliberate attempt to defraud the Court by a person who professed to be a medical man, and had signed a medical certificate. The person knew the penalty of such an offence, for instead of signing in the ordinary way, he made some mysterious-looking letters which appeared like "M.R.C.S.," but which in reality were "M.N.G.S." Fortunately, the judge detected the fraud, and the possible consequences of its perpetration were thus averted. It may be mentioned that the defendant was committed to prison for thirty days, and an application to suspend the warrant was refused.

Syphilitic Re-infection.

The subject of syphilitic re-infection is interesting from several points of view. A striking instance of the kind has just been recorded by Eichhorst, of Zurich. The patient was a man, æt. 23, who in January, 1893, had sexual connection, as the result of which he contracted simultaneously both gonorrhœa and an indurated chancre on the prepuce. The syphilitic symptoms pursued the ordinary course, and during the secondary stage the patient on several occasions presented himself at the hospital suffering from roseola and condylomata of the mouth and anus. On September 16th of last year he was quite free from any syphilitic manifestations. In about the third week of December, however, he again had sexual intercourse, and three days afterwards gonorrhœa for a second time developed. Moreover, towards the middle of January of the current year he returned to the hospital with a new indurated chancre situated on the right half of the prepuce. Some weeks subsequently to this re-infection a roseolous rash and mucous tubercles again appeared. The chief interest in the case, as pointed out by the author, was the short period which intervened between the infection and re-infection. In this particular, perhaps, the case is a unique one.

Sir J. C. Bucknill, F.R.S.

As has already been announced, the Queen has conferred a knighthood on Dr. J. C. Bucknill, F.R.S., in consideration of the part he took forty-two years ago in starting the Volunteer Force in the County of Devon. The services of Dr. Bucknill were brought under the notice of General Sir Redvers Buller, who undertook to place the particulars thereof before the

Secretary of State for War. This having been done, the latter official communicated with the Prime Minister, and when Lord Rosebery had laid Dr. Bucknill's claims before the Queen, Her Majesty graciously intimated her desire that the honour of knighthood should be offered the "Father of the Force." From our contemporary the *Devon and Exeter Gazette*, which all along has taken a very active part in promoting the public recognition of Dr. Bucknill's services, we learn that our *confrère* was born at Bosworth in 1817, and was educated at Rugby, and received his medical education at University College, London. He subsequently graduated at London University, and in time served the office of Censor, Councillor, and Lumleian Lecturer at the Royal College of Physicians. In 1844 he was appointed first Medical Superintendent of the Devon County Asylum at Exminster, and it was while filling this post that he conceived the idea of the Volunteer movement. In 1862 Dr. Bucknill left Devonshire on being appointed Lord Chancellor's Medical Visitor in Lunacy, which office he resigned in 1876. One of his sons is Mr. T. T. Bucknill, Q.C., Recorder of Exeter, and Member of the Epsom Division of Surrey.

The Council Election at the English College of Surgeons.

The Council of the Royal College of Surgeons of England has fixed Thursday, July 5th, as the date of the annual election of members to the Council. Already signs are not wanting that some activity is taking place in regard to the contest. Probably, with the recent opposition promoted by a certain number of the Fellows against the Association of Fellows, the election this year will be of more than ordinary interest. Upon its result will, perhaps, depend whether the reforming body of Fellows or the advocates of the anencephalous policy will be able to exist independently of each other. The struggle, of course, will be one for the supremacy, and while it is to be deplored that any section of the Fellows should have lent their support to a milk-and-water opposition, it is, nevertheless, satisfactory to learn that the flourish of trumpets with which the new opposition was started has made no permanent impression, and that the reports from influential sources point to the fact that the election at the College in July next will again be in favour of the reforming candidates.

The Council Election at the Irish College of Surgeons.

The list of candidates for seats on the Council for the election which takes place on the 4th of June is complete, and the voting papers have been issued to the Fellows. Mr. Thornley Stoker, the Vice-President, takes the Presidency, unopposed, and Mr. William Thomson, Surgeon to the Richmond Hospital, and recently Surgical Examiner in the College, becomes Vice-President without contest. Neither Mr. Hamilton, the outgoing President, nor Dr. Kidd seek re-election —which is to be regretted—and as a seat has been vacated by the appointment of Dr. Myles as an Examiner, there will be three vacancies besides those which may occur in the contest. For the vacant seats the competitors are—Dr. Archibald H. Jacob, recently Secretary of the Council; Dr. Purefoy and Dr. Cranny, representing the Gynæcological speciality; Mr. Sherlock, to represent Dentistry; Dr. Auchinleck, Professor of Forensic Medicine in the College; Dr. J. H. Scott, of the Adelaide Hospital; and Mr. Chance, Surgeon to the Mater Misericordiæ Hospital. We believe that Mr. Thompson, of the Omagh Infirmary, has also sent in his name. There are thus 25 candidates for 19 seats on the Council.

A New Objection to Vaccination.

Novelties of all forms, shapes, and sizes are usually expected from America, and attention has just been drawn to a perfectly novel objection which has been urged against vaccination. A Miss Robusta M. Strong was asked, so it is reported, why it was that she and so many other physically cultured young ladies declined to be vaccinated. Her reply was: "I do not see how I can give up my Indian clubs; and then, you know, I can't possibly spare my bicycle!" Evidently Miss Robusta M. Strong's parents had an eye to eventualities when the baptismal rite was performed upon her—the association of names is attractive. Possibly in the future, further developments of the kind will come into use. For example, Miss Flexora P. Long, or Miss Palmaris B. Short would presumably not sound to be odd or uninteresting. Again, in the case of males, Mr. Tibialis Anticus Legge, or Mr. Astragalus Foote might be worthy of adoption. But these suggestions are not made with a view of extending the opposition against vaccination.

Dental Matters.

The General Medical Council has not taken enthusiastically to the powers vested in it by the *Dentists' Act*, probably because the additional duties imposed thereby are of a troublesome and thankless nature, and also because the Dentists' Fund is at present a minus quantity. The Royal College of Surgeons in Ireland has been brought to book for granting its licence to practise dentistry without exacting any proof of practical training on the part of candidates, and this led the committee to suggest that it was about time to put into force the powers conferred by the *Act* in respect of the visitation and inspection of examinations. Unfortunately this means money, and there happens to be none available for the purpose. Until and unless this is forthcoming, therefore, the examinations will have to go uninspected, a condition of things which should exercise the mind of the Dental Association. The Council has also thought fit to repeat its warning as to advertising by dentists, in the shape of a formal declaration that the issue of advertisements containing claims of superiority over other dentists, or unfair depreciation (is there any fair depreciation?) of them "may easily be carried so far as to constitute infamous or disgraceful conduct in a professional respect." A very picturesque display was made of such "ads." by Mr. Carter, who had brought with him a portfolio collection. The suggestion that one or more dental representatives should be added to the Council, though reasonable enough in itself, does not commend itself to that body as at present constituted, and it will only be by the direct action of Parliament, if at all, that this innovation can come to pass.

Expurgation of the Profession.

The General Medical Council has, apparently, entered with zeal upon the task of suppressing illicit practice. They, at their meeting last week, weeded out three practitioners for the offence of "covering" unqualified persons—one for "covering" a company who called themselves the "Progressive Remedy Institute"; one Zurich lady doctor for violating her obligation to the Irish College of Physicians not to advertise. A further new departure was made by the Council in expunging a practitioner for the offence, simply, of advertising. This person "ran" an epilepsy business by the agency of a pamphlet and a secret remedy, and it goes without saying that his advertisements were thoroughly blatant, vulgar, and untruthful. The question before the Council was whether, even if advertising be not necessarily "infamous in a professional respect," these particular advertisements were so. The Council, after deliberation, took the plunge, and expelled the culprit. We hope that their action will be sustained if an appeal is made to the law, but we entertain doubts.

Large Fees for Medical Men.

A report is current in America that the medical man who attended Mr. Vanderbilt on his yacht during a four months' trip was paid a fee of £12,000 (60,000 dols.) This is at the rate of £3,000 a month, or rather more than £700 per week, or, say, one hundred guineas for each day of the week. A voyage under such circumstances, of course, might not be altogether devoid of anxious work, yet, still, the mere recollection of the remuneration which each day brought with it would be ample to render any discomforts of the mind tolerable. Moreover, to leave the yacht virtually with a cheque which to many would represent a fortune, the achievement having occupied no longer than four months, would be something equivalent to establishing a record in the history of fees paid for professional services. In short, however the matter might be looked at by the fortunate medical adviser of such a wealthy patron, reflections of a most consoling description could not fail to be aroused in his mind. We also hear that Dr. Galezowski, of Paris, will receive £5,000 for his visit to Persia in order to attend the eldest son of the Shah.

The Birthday Honours.

In addition to the name of Dr. J. C. Bucknill, whose Knighthood was announced in the list of birthday honours, we note the names of the following members of the medical profession: Mr. F. Seymour Haden, F.R.C.S., who receives a knighthood, together with Dr. Grainger Stewart, Physician in Ordinary to the Queen in Scotland, and Professor of Physics in the University of Edinburgh. Among Colonial honours conferred we notice the name of the Hon. Arthur Renwick, M.D., Commissioner for New South Wales at the recent Exhibition at Chicago, formerly Minister of Mines, Minister of Public Instruction, and now Member of the Legislative Council of that Colony. The general impression is that the distribution of honours has been somewhat meagre, a fact which becomes more apparent still when it is recollected that no new peer has been made, and only half-a-dozen persons have received the distinction of a baronetcy.

A New Salt of Quinine.

At a recent meeting of the Royal Academy of Medicine of Madrid, Señor Hernández Briz brought under the notice of the Academy a new salt of quinine; which he says is a compound of the alkaloid with hydrochloric and sulphuric acid. He gives the formula as $C_{20}, H_{24}, N_2O_2, +2Hcl+H_2, SO_4+3H_3O$. The salt is a pale yellow, or amber colour, readily soluble in water, and it produces no irritation when used hypodermically. Sr. Briz has been using the salt since its discovery in December, 1892. In fever ravages the effects were very pronounced. A severe case of typhoid in a man over 30 years, high temperature, dry tongue, marked weakness, and total loss of memory, was treated with the salt by injection, and recovery resulted slowly but perfectly. Some other cases are given, but they affect the question very little, as the curative effects were evidently due to the alkaloid. The salt is prepared by Señor Coipel, of Madrid.

Anatomy for Tommy Atkins.

The thirst for scientific knowledge appears to be pervading all classes of the community. That particular form which is known as ambulance instruction has been with us for some years. The latest development is a scheme to teach British soldiers the elements of anatomy—at any rate so far as the position of the chief arteries is concerned, and the means of arresting hæmorrhage. It is a tolerably well ascertained fact that a majority of deaths on the battlefield are caused by the loss of blood before the arrival of surgical aid. In order to meet any intellectual difficulties that might prevent the average soldier from picking up his anatomical outlines, someone has made the grotesque suggestion that the lines of the arteries should be tattooed on their bodies!

Spasm of the Glottis.

Dr. Moreno Zancudo has published (*El Siglo Medica*) two interesting cases of spasm of the glottis produced by reflex irritation of impacted fæces in the colon. The first case was that of a young woman of a hysterical nature who was a confirmed dyspeptic. At first the attacks, which occurred at night, were treated with chloral and bromide in full doses, and the local application of hot sponges over the larynx. The detection of a loaded colon decided Dr. Zancudo to give a brisk saline purge which not only emptied the bowel but got rid of the laryngeal spasms. The second case, which occurred in the practice of Dr.

Manzaneque is more severe, the spasms occurring at short intervals. The saline treatment, suggested by an impacted colon, was followed by the discontinuance of the spasms. The tendency of impacted fæces to cause spasms by reflex action attracted the attention of John Abernethy who recommended purgative treatment early in the century, and now from all quarters of the medical world we almost daily receive confirmation of the necessity of keeping the colon as aseptic as possible.

Mr. Gladstone's Eyesight.

The extraction of the cataract from Mr. Gladstone's right eye was successfully performed by Mr. Nettleship on the 24th inst. Cocaine was employed, and the operation was in all respects uncomplicated. Everything has progressed satisfactorily, no untoward symptom having so far developed. This being the case, it may be said that a successful result has now been definitely secured. Within a few weeks Mr. Gladstone will, in the ordinary course of things, be provided with lenses for near and distant vision, and the failure of sight which has for some months interfered with his usual pursuits, will so far, indeed, as one eye is concerned, have been removed.

Bogus Diplomas.

We must congratulate the General Medical Council on the success of the steps taken to prevent the use of bogus degrees such as those granted by the "General Council of Safe Medicine" and to vindicate its position in the matter, and we trust that equal success will attend such further proceedings as may be taken to squelch this corporation in its entirety. It would, indeed, have been a more statesmanlike policy to have attacked the corporation first instead of frittering away energy and money in proceedings against individuals.

Before the Bar.

Some curiosity was excited among members of the General Medical Council by an "apparatus" of novel shape which figured in the Council room, and it was not long before an inquiring Scotchman sought to know what it might be. The apparatus in question proved to be a portable rostrum from which outsiders wishing to address the Council might do so with advantage. A defendant in penal cases is now literally made to stand in the dock, though the degradation is minimised by the fact that he is preceded in that elevated position by his prosecutor, and is followed there by his own legal adviser.

Dr. Althaus, having resigned the post of Senior Physician to the Hospital for Epilepsy and Paralysis, London, held by him for the past twenty-eight years, has been elected Consulting Physician to that institution; and Dr. Cagney, Physician to out-patients, has been appointed Physician with charge of in-patients.

The next important service medical appointment falling vacant is that of P.M.O. at Netley in July next, on the retirement, at sixty years of age, of Surgeon-Major-General Broke Smith. Surgeon-Colonel Archer, now in Nova Scotia, will probably succeed to the appointment, pending his promotion in November next, vice Giraud.

A person—said to be a doctor—residing in New York, has been found guilty of the murder by antimony and arsenic of a man whose life he had insured. He induced his wife to enter into a bigamous marriage with the victim in order that she might, on his death, claim the insurance money.

The annual meeting of the Royal Medical Benevolent Fund Society of Ireland will be held at the Irish College of Physicians on next Monday, the 4th June. The chair will be taken at 4.30 o'clock by W. G. Smith, M.D., President of the College.

The electric light has been introduced into the ophthalmoscopic room at Moorfields, and the old-fashioned Argand gas-burner has been displaced, to the great advantage of the surgeons and the patients.

The Medical Faculty of the Catholic University have nominated Professors Roche and McWeeney as delegates to the International Sanitary Congress at Budapest.

The Committee of the Great Northern Central Hospital have elected as their Secretary Mr. Lewis H. Glenton Kerr, late Assistant Secretary at the Middlesex Hospital.

Mr. Kearsley, M.P., has given notice to the House of Commons of a motion to appoint a Select Committee to inquire into the working of the Adulteration Acts.

A meeting is to take place at Salcombe to consider the proposal to erect a memorial to the late Dr. Alfred H. Twining.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Queen's Birthday Honours.—General satisfaction is expressed in Edinburgh with the honour just bestowed on the Lord Provost of that city, Sir James A. Russell, M.B., LL.D., F.R.C.P.E., F.R S. Ed., an honour which he has richly merited from his public services to the city. Graduating in 1868, M.B., C.M. Ed., with first-class honours, a few years later he acted for eight years as assistant to Sir William Turner in anatomy, and afterwards studied and lectured on sanitation in the Watt College. At present he is Her Majesty's Inspector of Anatomy for Scotland. He has been a member of the Town Council for fourteen years, a Bailie for nine, and Lord Provost for three. As lately as April last the University of Edinburgh conferred on him the degree of LL.D. in recognition of his merits as "a man of science, a man of affairs, a benefactor both to the city and to his ancient town's college."—Sir Thomas Grainger Stewart, M.D., F.R.C.P.Ed., F R.S.E., &c., Professor of the Practice of Physic in the University of Edinburgh, and Physician-in-Ordinary to the Queen for Scotland, is the recipient of another of the birthday honours, and one which was not unexpected.

Small-Pox in Edinburgh, Leith, and Coatbridge.—The small-pox epidemic has assumed rather alarming proportions in Leith, where last week no less than sixty-one cases of the disease were notified, and these are probably not the whole, as Leith is not under the Notification Act. In Edinburgh, on the other hand, the epidemic is being kept better in hand, although the numbers are slowly rising. Last week eighteen cases occurred. Dr. Littlejohn has deemed it necessary to send out to the practitioners in Edinburgh, in the name of the Public Health Committee of the Town Council, circulars requesting them to do what they can in the way of vaccination and revaccination of their patients, and especially of their dependents, to prevent a further spread of the disease. In the mining district of Coatbridge the epidemic is spreading, and the miners are freely availing themselves of the protective influence of vaccination.

Tyson's Drink-Cure in Glasgow.—Dr. (!) Tyson has deprived America for the time being of his valuable presence, and is now on a personally-conducted tour in Great Britain. Tyson, we understand, finds it necessary to come to this country, and so the Christian Institute (Keeley tried to open his course in London with a bishop in the chair, but this journal inconsiderately stopped the meeting) on Wednesday last was honoured with his patronage, and the population of Glasgow were told that their murky city could be rid of its drunkards, and these in turn would become respectable and useful citizens, at £6 per head! Of course the credulity of the public is proverbial, but we should have imagined his experience in Dundee was not sufficiently encouraging to look on Scotland as a likely field for his enterprise. However, the inevitable committee was appointed, the equally inevitable test cases nominated, and the inevitable report will follow in due course.

Glasgow Blind Asylum.—With the view of increasing public interest in the work carried on in the Glasgow Blind Asylum, the directors, on the 23rd inst., opened an exhibition of technical kindergarten work, physical drill, and vocal and instrumental music by the children and by the choir of the institution. The Asylum was thrown open to the inspection of the visitors, who thronged the building. The children displayed their skill in wood-carving and the other industrial work carried on for commercial profit. Machine-sewing by motive power was shown, and illustrations were given of the wonderful proficiency acquired by the inmates in basket-making, chair-caning, cork fender-making, spinning ropes and twines, and the manufacture of cushions, mattresses, and bedding of every description. During the day a programme of vocal and instrumental music was gone through.

Glasgow Medico-Chirurgical Society.—The following office-bearers were elected at the recent annual general meeting of this Society:—President, Dr. Hector C. Cameron. Section of Medicine: Vice-President, Dr. Jas. Finlayson; Councillors—Drs. W. A. McLachlan and Jas. W. Allan; Secretary, Dr. C. O. Hawthorne. Section of Surgery: Vice-President, Mr. A. E. Maylard; Councillors—Drs. Macphail and Jas. A. Adams; Secretary, Dr. John Barlow. Section of Pathology: Vice-President, Dr. Charles Workman; Councillors—Drs. T. K. Monro and L. R. Sutherland; Secretary, Dr. R. M. Buchanan. Section of Obstetrics: Vice-President, Dr. Murdoch Cameron; Councillors—Drs. Jardine and Geo. Halkett; Secretary, Dr. Lawrence Oliphant; Treasurer, Mr. Henry E. Clark; General Secretary, Dr. Walker Downie.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

COUNTER-PRESCRIBING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Since I wrote to you objecting to the legalisation of counter-prescribing, I have had a conversation with Sir Benjamin Richardson on the subject. Though he has not yet convinced me that the proposal will be free from injury to the interests of the profession and of the public, it seems to me that the proposition should receive a full and fair consideration. Sir Benjamin's idea is apparently intended to benefit both the profession and the sick suffering from minor ailments, or in an emergency, and I am glad to learn that he is to explain the matter in the *Asclepiad.* Nothing but good can come from a thorough discussion of his suggestions.

I am, Sir, yours, &c.,
Norman Kerr, M.D.

42 Grove Road, Regent's Park, London, N.W.
26th May, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Your letters of last week on counter-prescribing open up a wide field for inquiry and reform. In approaching the subject one is led to ask, What is the principle of medical qualification? If the answer be to protect the public against medical treatment by unqualified men ignorant of medical matters, then the prescribing of medicines by chemists stands condemned.

Think, Sir, of the disasters which are invited by the prescribing of arsenic in an acute eczema, by the use of a sulphate of zinc lotion for an ulcerated cornea, by the administration of a purgative in typhoid, or by giving a depressant in febrile cases with weakened heart, all familiar and everyday instances of counter-prescribing.

Facta non verba should be the motto of the profession in dealing with this public danger.

I am, Sir, yours, &c.,
David Walsh, M.B.

62 Welbeck Street, W.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In discussing this question and suggesting the intervention of the Legislature, it is necessary to bear in mind that Parliament will certainly never take action in any case merely for the protection of the profession, or for any other purpose not purely to the advantage of the public. The practice of medicine and surgery for gain in any department will never be forbidden to unqualified individuals so long as leading statesmen adhere to the principles they have so long acted upon. The most that may be hoped for is the passing of laws which shall prevent the assumption of titles by unqualified practitioners, and shall also put a stop to the employment of methods whereby quacks although not adopting professional designations are able effectually to palm themselves off on the public as legally-qualified men. This much may be reasonably hoped for, since legislation of the kind has been carried with respect to veterinary practice. In numerous cases unqualified individuals have been convicted under the Veterinary Act and heavily fined for merely displaying a sign inscribed "Veterinary Forge," it being held that this was calculated to lead the public to take the practitioner for a registered veterinary surgeon. No attempt is ever made to prosecute quack proprietors of medical establishments worked under the grossest false pretences. So weak is the law and so lax its administration as regards titles that even every unqualified quack dentist is now a "Dr." and in no department of practice is there the least difficulty in the way of a quack who chooses to adopt a designation sufficient to deceive the public.

I am, Sir, yours, &c.,
S. E. R.

May 24th, 1894.

A PERPLEXING DIAGNOSIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Would you, or any of your readers give an opinion as to the cause of death in the following case:—

A. B., a healthy young man, æt. 20, of healthy parents, got two or three blows of a stick on the left side of head near vertex, on Nov. 13th last. These blows caused ordinary scalp wounds, which healed in two weeks under domestic treatment. About a fortnight afterwards the man was laid up for about a week with headache and pains in the bones, and was believed to have influenza. He soon got better, was able to go about, take long journeys and deemed well. Visited next town (7 miles off) more than once without inconvenience. Dec. 22nd visited town all right, did his business, took a moderate share of drink, and set out for home. After walking about two miles homewards he complained of not being well, sat in a car and got drowsy, became unconscious, and comatose during the night and next day, and died at 3 o'clock a.m. on 24th December.

Condition at 7 p.m., 23rd, temp. 10·7°, limbs all paralysed, pupils much contracted; death supposed to be connected with the assault. Post-mortem ordered, and held May 15th inst.

Post-mortem condition (about 4½ months after death). Head only examined owing to decomposed state. Remains of ordinary scalp wounds.—Calvarium removed: no fracture, no ruptured blood vessel, no extravasated blood, membranes normal. On opening the membranes the brain was of a thick creamy consistence from decomposition, of uniform colour; base: no fracture. Membranes on pons and round anterior half foramen magnum inflamed; no serum or blood except of the latter a small rust colour, quantity about enough to tinge lightly a "threepenny bit."

Two medical men made the post-mortem (I was one). Conclusions:—

Both agree—no connection with the blows. Differ as follows: opinion (1) hæmorrhage at the base of the brain; 2) serous effusion from the inflamed membranes on the pons, pressing on cerebellum at foramen magnum and disappearing after death, probably gravitating into spinal canal; suspected lesion at pons since attack of influenza, stirred up on 22nd Dec. by (a) some drink, (b) some mental excitement on the way home and (c) the effects of the travelling seven or eight miles in the cold of the night of that 22nd Dec.

Any light thrown on this case will much oblige.

An Enquirer.

P. S.—Are not cerebral lesions rather common after influenza?

◆

THE "ANTI-MEASLY" TREATMENT OF MEASLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—One hears and reads a great deal about the "anti-syphilitic" treatment of syphilis; so, to show the absurdity of the procedure, I shall, with your permission, say a few words about the "anti-measly" treatment of measles. Both syphilis and measles are germ diseases, and the remedy which rapidly cures both is the solution of the biniodide of mercury in iodide of potassium. The plain and evident reason why syphilis is curable by such treatment is that the drug kills the germs; and it is the more readily able to do this in its circulation through a fibrin-containing fluid, in virtue of the fact that it is held in solution by a drug which diminishes the tendency to the formation of fibrin—potassic iodide.

This view was advanced by me in 1886, in the *British Medical Journal*, and it was based upon previous communications in *your* columns in January and February, 1886, upon "A new System of Treatment through the Blood"; and also in a communication to your columns on September 7th, 1887, entitled "Principles *versus* Specifics." The views there advanced, and still held by me, have never been refuted by anyone. Indeed, their soundness has never been called in question.

I write now more especially of the action of Dr. Leslie Phillips in his statement to the medical publication known as the "Year-Book of Treatment for 1890." The treatment he in a few words condemns as having been found useless in the London Fever Hospital, is the same "anti-scarlatinal" treatment which I have heard him refer to so enthusiastically and confidently in the curative treatment of syphilis.

In this action Dr. Phillips virtually accuses me of rashly vaunting a remedy or of being no clinician. Unfortunately for Dr. Phillips's position, the testimony to the efficacy of this "anti-syphilitic" treatment of diphtheria, scarlet fever, measles, whooping-cough, &c, is too strong to be lightly thrown on one side with a few words. The mischief of the matter, however, lies in the quotation of remarks falling from the lips of men occupying such prominent places as physician to a London fever hospital; and as this is being done by Dr. Roberts, I understand, I wish now to protest, in the name of rational treatment, against any such condemnation, seeing that this treatment has received the strong support of men like Clement Dukes, of Rugby; Gabb, of Hastings; Luff, of St. Mary's Hospital; and a host of others too numerous to mention.

It is my unpleasant duty, therefore, in regard to this statement in the "Year Book of Treatment for 1890," to return Dr. Phillips the compliment, and accuse him either of *suppressio veri*, or of being "no clinician"; and at the same time to call upon him and those who have similarly condemned this accredited and long-tried germicidal treatment of specific febrile disorders, to produce the evidence they have showing that it *can only kill one kind of germ.*

I am, Sir, yours, &c.,

C. R. Illingworth, M.D.

May 23rd, 1894.

QUALIFIED ASSISTANTS AND THE SANCTITY OF A BOND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The usual bond between principal and assistant is a subject upon which, as far as I know, the profession has never expressed itself with sufficient determination and clearness; and the fact that many members of the profession, have suffered from the manner in which law courts have treated this question is, I am sure, justification enough for my calling attention to the subject.

One would be well within the mark to say "that there are few medical men in practices sufficiently important to require assistance, having 15 or 20 years' experience, who have not suffered through the unprincipled behaviour of one or more of their assistants." Assistants who have broken through every tie of honour, and have started practice in opposition to their principals.

What I am stating is either a fact, or a misrepresentation, if the latter, I am slandering an honourable profession; if the former, then a noble profession is disgraced by a number of men, who had far better for the profession's sake, be excluded or ignominiously lopped off from the body corporate.

The question at once arises. How is this great abuse to be dealt with? and it is with a view of solving this question that I venture to trespass upon your valuable space. This question is a vital one, to a large body of general practitioners, and particularly to that class of general practitioners, which having learned its profession, is not afraid to practice it.

How can a practitioner, of the class I refer to, undertake all the operations and manipulations of a varied practice, without a qualified assistant to administer anæsthetics, and assist in the details appertaining to such cases. He simply cannot do it, and yet nearly all the practitioners of this class, of 20 years' standing, with whom I have conversed on the subject, have told me the same thing, viz., that after years of patiently working up a position and reputation, some assistant they have employed, has turned traitor, and commenced practice in opposition, robbing them seriously of patients, and introducing an element of discomfort, very often at a time of life and under circumstances when such an eventuality falls as a very severe blow.

And now as to the remedy:—

1. I do not consider any ordinary court of law at all the place for a question such as I have named to be settled in.

2. Such professional questions ought to be settled by a really high class medical tribunal.

3. I would suggest, that a body such as the Medical Defence Union should carefully sift such cases, and if after unbiassed and mature consideration, a breach of faith should be proved, then the General Medical Council should be urged to try the case as one of professional misconduct, and deal with the delinquent in a fitting manner. If this were done, we should very soon cease hearing of the shameful breaches of trust which at any time are a disgrace to an honourable calling. A higher tone of conduct would soon be established, and certainly one great blot upon the escutcheon of the medical profession would be removed.

In conclusion, I cannot do better than quote from a letter received this morning from an influential member of the profession regarding the subject of qualified assistants. He says, "If men will only speak out properly and courageously, the profession has a chance of doing itself an enormous amount of good by raising its tone, and showing that it is not tainted deeply with so-called commercial morality. We are a nation of shopkeepers, but that is no reason why a profession should be guided by the instincts of petty tradesmen."

I am, Sir, yours, &c.,
Alfred Swann, M.D.,
Hon. Surgeon to the Batley Hospital,
Medical Officer of Health for the Borough of Batley, &c.

Obituary.

WM. WAUGH LEEPER, M.D. Edin., L.R.C.S.I.

By the death of Dr. Leeper, of Loughgall, co. Armagh, the profession in the North of Ireland has lost an able and skilful physician. Dr. Leeper graduated in Edinburgh University in the year 1844, winning the gold medal for his graduation thesis on "The Pathology of Tubercle." He then proceeded to London, where he acted as assistant to a general practitioner for six months, after which he was appointed a surgeon in the P. and O. steamship service, first on the *Iberia*, and afterwards on the *Bentinck*. He remained in the P. and O. service for nearly three years, giving it up to reside in Calcutta, in which place, however, he only remained a short time. Returning to Ireland in 1847, he was appointed Medical Officer to the Blackwatertown Dispensary, and soon after was also elected to the Loughgall Dispensary, both of which appointments he held until the following November, 1847, when he resigned his connection with Blackwatertown, and from that time up to the day of his death held the position of Medical Officer in Loughgall Dispensary. He was Visiting Physician to the Retreat Lunatic Asylum. He published numerous papers in the medical journals. He had a very extensive private practice in co. Armagh, and his consulting practice extended over several counties, as he was known and appreciated by his medical *confrères* as a sound and practical physician, whose opinion was always carefully arrived at, and whose medical knowledge was fully abreast of the times. The circumstances attending his last illness and death were of the most pathetic character: he was seized with paralysis while in the act of applying the forceps in a difficult case of labour, became almost immediately unconscious, and died on the fourth day, without having recovered consciousness. He had frequently expressed a desire to be relieved from the worry and care of dispensary work; but as he knew that a pension would not be granted to him after 46½ years' unremitting toil in dispensary work, he was compelled to labour on until death released him on Wednesday, 16th May, 1894.

ASYLUM REPORTS.

THE ROYAL EDINBURGH ASYLUM.

The annual report of the Royal Edinburgh Asylum, in which Dr. Clouston discourses with a free hand, is up to its usual mark in its range of topics and popular interest. It is not too much, however, to say that the general medical reader, and even the medical officers of other asylums may peruse it with much interest and profit. Many asylum reports would be saved the fate of the waste-paper basket if their authors would free themselves from the restraint of shyness and dread of public criticism and allow themselves to think aloud. Many will recognise in not a few of Dr. Clouston's expressions of opinion an echo of their own thoughts and conclusions. At the same time it must be admitted that Dr. Clouston presents these in a graphic and telling fashion that invests them with a charm of originality and conviction. That Morningside has flourished and is still flourishing under Dr. Clouston's wise and beneficial *regime* this year's report again testifies. His active and enterprising spirit has carried him through much in the last twenty years. In two decades the East House and the West House have been reconstructed and renovated, and the new Craig House has been erected, and is now partly occupied. Of the total sum of £154,000 spent in the twenty years for such purposes £90,700 has already been paid off. This, be it remembered, is done by the appropriation [illegible] private patients, not by assessment laid on the [illegible] One striking fact brought out by Dr. Clouston is that the cost per pauper patient for rent is £3 18s. 6½d., while in the District Asylums for pauper patients erected in Scotland it is £9 12s. 5d. In Glasgow and the West of Scotland there is now being spent some £320,000 in providing new asylums because there is no such provision made in Glasgow as is done in Edinburgh. As a matter of fact the Glasgow Royal Asylum will soon cease to accommodate pauper patients at all. Dr. Clouston does not mean to reflect on the management at Gartnavel, in making this comparison. What he is driving at is this, that certain Edinburgh ratepayers or their representatives seem to grumble because they are not allowed to spend as much as they are doing in Glasgow in order that they might have the direct control of the asylums. He forgets that the comparison is strained, for in Glasgow and the West the population is very large, and the Edinburgh expenditure need not be more than £100,000. This, it is true, is a large sum of money to throw away, and as Dr. Clouston observes it would be sacrificing the ratepayers' interests to a theoretical desire for uniformity of lunacy administration. It is none the less a fact that the management of the Royal Asylum is that of a close corporation which is only indirectly affected by public opinion, and while the record of the Edinburgh, Aberdeen, and Montrose Royal Asylums is one that would pass the pit of the best representative board to beat, the day of close corporations is threatened. Like the House of Lords they do not, however, seem to be within measurable distance of extinction, and Dr. Clouston's words of plain common sense may avert the catastrophe for some time to come.

Dr. Clouston takes credit, and rightly so, for a rapid movement, a large turnover of patients, chiefly the result of boarding out harmless and chronic cases, or transferring them to licensed wards of poorhouses. He compares his results—every man must crack up his own asylum—with those of the whole of the asylums of Scotland. Here are his words: "While in the whole of the asylums of Scotland the new cases sent each year stood to the average number resident at one third, with the Edinburgh Asylum it was over one-half, and taking the rate paid patients it was this year two-thirds. In no other institution in Scotland did the same ratio prevail. Now it is an old axiom that statistics may be made to prove anything. We do not dispute these facts; but we protest against them being made a basis of comparison. The following rider should have been appended to such a statement:—1. Morningside has recently been passing through a period of unusual activity in boarding out chronic cases and creating vacancies for new cases. 2. Morningside has been adding to its accommodation for private patients. 3. Morningside is in a populous district to which rural immigration is constant. Rural immigrants when they become insane are transferred to county asylums from Morningside—county asylums have rarely such vacancies, Morningside has a large number. 4. Morningside can relieve congestion further by sending less troublesome cases to licensed wards in the city, and such institutions are rare in the country. 5. In populous centres such as that from which Morningside draws its cases, insanity takes more acute forms, often of brief duration, and the death-rate is higher. Here, also, is another explanation of more vacancies arising in Morningside than in county asylums. Much more might be said on the subject; but it is enough to say that Morningside is not the only Scotch asylum whose history can show a period of high admission rates. Dr. Clouston generalises freely on the question of family inheritance, on the absurdity of the boast so frequently uttered "our family at least is free from insanity." "Insanity," he observes, "is by its nature and by heredity, own brother to epilepsy, idiocy, convulsions, dipsomania, paralysis, and St. Vitus dance, while it is first cousin to neuralgia, asthma, diabetes, and nervous exhaustion." He has made an inquiry into the family history of eighty-three families taken at random in a country parish in Scotland, all the members of which were personally known to him for three generations. He assures us that he took every family he really knew, and that there was no selection; but there must have been selection if he took only those personally known to him, and what about those left out? They only had one vice apparently *love of money*, and did not drink. Vice in its grossest forms was unknown; but the district was isolated, and inter-marriage was common. Of 83 families he found some mental deviation from the normal slight or marked in 41. We agree with him that there is little room for boasting and much for manly common sense and sympathy; but in this case, whether it be due to love of money, or inter-marriage—both great evils, Dr. Clouston's investigation of one remote parish, and its result must not be taken too seriously. The facts are worthy of investigation, and here as elsewhere, now and in the past, Dr. Clouston has given us abundant food for reflection.

DERBY BOROUGH.

THE Reports of the Committee, the Commissioners, and the Medical Superintendent are all very satisfactory. Dr. Macphail reports that the percentage of physical impairment in the admissions is large; but in most asylums this phase of mental disease is considerable. The spread of a desire for a better-trained staff is therefore natural, and Dr. Macphail is quite alive to the importance of training and a general levelling upwards of his attendants and nurses, and in this he has the support of his Committee, which is very encouraging. The strength of the staff is good, much better, indeed, than in many asylums.

HOLLOWAY SANATORIUM.

THE Report of this excellent institution indicates abundently that there is no thought of standing still on the part of the management. Dr. Rees Philipps does not believe in finality in the perfecting of the asylum machine, and each annual report as it appears is "chokeful" of new ideas and experiments for the good of the insane. Boarding-out, massage, Swedish drill, boarding of friends of patients, and allowing them to fuse into the life of the house—these are but a few of the ideas brought to light in this report. There can be no question that this hospital is serving its purpose admirably, and much of its success is due to the enterprise and enlightened views of the Medical Superintendent.

KILLARNEY DISTRICT ASYLUM.

THE Report for 1893 is carefully compiled, and gives varied information to an extent unusual in asylum reports. While every economy is being exercised in the management, it is desirable to point out that economy may be purchased *dearly* in the end, and here the maintenance is surely too low. It might be well to bear in mind that not many years ago the English asylums raced each other for the lowest place in the scale of board rates. Happily that foolish craze is over. Dr. Griffin is evidently an economist; but we doubt not he has that medical spirit also which puts the interests of his patients before *all* other considerations.

METROPOLITAN ASYLUMS BOARD—REPORTS FOR 1893.

THE work of this Board, and the manifold duties which lie before it, is quite beyond the conception of the average citizen, and to note the size and dip into the contents of its volume of annual reports is a task not to be lightly undertaken. The first part of the volume consists of the Report of the Statistical Committee, and the observations in this report are brief, to the point, and of particular interest in many cases. Two observations of practical and medical interest may be quoted: 1. In the course of the year 732 patients, 3·9 per cent. of the total admissions into fever hospitals were found to have been sent under a mistaken diagnosis. 2. The percentage of infection of the staff was 5·2. Of 2,484 persons employed during the course of the year 130 fell ill with fever, diphtheria, or measles, and two died. Part II embraces the reports of medical superintendents of fever hospitals, together with fever statistics. Subsequent parts deal with small-pox hospitals, imbecile asylums, schools, &c. The volume is full of interesting reading, and along with it are sent out maps of the sanitary districts of London, graphically illustrating where the infectious diseases are prevalent, and the relative intensity in different places.

Literature.

THE MEDICAL ANNUAL AND PRACTITIONER'S INDEX, WORK OF REFERENCE FOR MEDICAL MEN. (*a*)

THIS, the twelfth year of publication of the "Medical Annual" finds it still growing in favour with the members of the medical profession. The arrangement of the matter, the number and excellence of its illustrations, the freedom from bias for or against any theory of medicine, the care taken to bring the information to the most recent development of science, call for unstinted praise. The editors of the sections are known throughout the world of medicine; they include some of the most distinguished American and Continental writers. Of British editors, to name some without naming all might appear invidious. We may, however, say that the list includes some of our most distinguished medical authorities. For the purpose of the Annual the medical literature of the world is laid under tribute; it is condensed, sifted, annoted, and edited. Nothing of importance escapes notice, and the reader is saved wading through columns of padding, finding just the essential statement placed with sufficient fulness for his guidance and a reference to its source for fuller information, if he so desires. Along with all this there is the healthy corrective of editorial annotation to the too sanguine or too pessimistic view put forward by the author.

We have just one fault to find, but it is a big one. We refer to the delay in publishing. Some efforts should be made to produce the book in January; but when it does come we are bound to confess it is unrivalled as an Annual.

THE HUMAN ELEMENT IN SEX. (*b*)

THE very title of "The Human Element in Sex," by Dr Elizabeth Blackwell, is calculated to attract attention, and a glance at the table of contents will rivet it. Writing from the standpoint of the Christian physiologist, the authoress discusses the physiology of morality and the pathology of immorality with a frankness which is as refreshing as it is unexpected. She laments—as so many have lamented before her—"the ignorance of parents, and above all of mothers, of the facts of sexual physiology." That reproach will certainly not be applicable to mothers *in esse* or *in posse* who have read, marked, learned and inwardly digested the authoress's brief but unvarnished words, for she has done her best to enable her readers "with propriety, purity and reverence, to study the action and uses of our sexual powers." After a few discursive remarks on the distinctive character of human sex the authoress discusses the equivalence of the sexual functions in the male and female. In this chapter her views do not strike one as being quite "up to date," when for example, she affirms that there is no rudimentary part corresponding to the uterus in the male, or, further on, when she refers to the active vitality of the spermatozoa "which in the work of procreation is obliged to traverse long and winding passages in order to come into contact with the ovum which is advancing to meet it," evidently referring to the Fallopian tubes, and ignoring Lawson Tait's explanation of the function of the healthy tubal cilia in keeping the germ-cell out of these tortuous paths. In the chapters on "the abuses of sex" the authoress drives full tilt against the "unnatural practice," (elsewhere branded as an "ugly mutilation") of circumcision. This she does apparently on the general principle that if Providence has persistently endowed male mankind with a prepuce, this structure necessarily serves some useful purpose, in fact, she enters a formal protest against the assumption that Nature can be improved upon. We cannot honestly say, however, that she has advanced any weighty argument against the practice, for we do not attach the same importance as does the authoress to the "keen sensitiveness" of the part normally protected by an unmutilated foreskin. The authoress retraces the picture of the mental and physical degradation associated

(*b*) "The Human Element in Sex." By Elizabeth Blackwell, M.D. Geneva, U.S. London: J. & A. Churchill. 1894.

with sexual abuse, but she might have spared us the harrowing details of the sad case of "an intelligent and pious lady, once a Sunday school teacher," dying from the effects of forty years inveterate masturbation. In her condemnation of promiscuous indulgence in what Milton described as the act which

" . . . by lewd and lavish act of sin
" Lets in defilement to the inward parts,"

the authoress points out that promiscuous intercourse can never be freed from pathological risks, "the special structure of the female body, rich in secreting glands, in folds, in power of absorption, cannot be treated as a plane surface, to be washed out and labelled 'safe.'" She shows with logical precision that continence does not beget impotence in either sex, and that love may exist in all its plenitude quite irrespectively of the act which to some women is either indifferent or repugnant. Altogether the work is as interesting as it is instructive, though one cannot help considering for whose instruction it is intended. Finally we must congratulate the authoress on the courage with which she has grappled with various delicate and debatable problems.

Special Articles.

THE CAUSES OF NEURASTHENIA.

The causes of that malady known as neurasthenia appear to be very complex, judging from a paper read before a recent meeting of the St. Louis Medical Society by Dr. L. N. Love. To begin with, it is pointed out that this latter-day affliction is seldom found among those who live below the upper crust of the social world, and mainly because the manual labourers of the world as a rule are not disturbed by the three A's which confront a large proportion of those in the higher walks of life, namely, Ambition, Avarice, and Anxiety, and are at the same time, able to keep clear of the three L's, namely, Laziness, Luxury, and Lust. But the majority of the cases, we are told, of so-called neurasthenia are either victims of nerve weariness dependent upon misdirected energy without proper rest at proper intervals, or nerve poisoning, the result of constipation, improper food, and accumulation of effete products of tissue change—leucomaines and ptomaines. The latter condition is attributed to a disposition to use the stomach too much and the rectum too little, and the failure to appreciate the importance of pure air as a rejuvenator of tired and poisoned nature. Again, neurasthenia may arise from nerve demoralisation, resulting from unrelieved peripheral irritations, while cold, malaria, and rheumatic conditions are also potent factors in its causation. But constipation, in the opinion of the author, takes a very high place in relation to the etiology of this affection. "When we recall the fact," he says, that 90 per cent. of the women of the world are more constipated than the traditional owl, we realise what room there is for improvement in this direction." Undoubtedly, with only 10 per cent. of the women of the world in the condition of an owl which requires no purgative, there must be vast room for improvement. With no particular figures to go upon, however, we must confess that the percentage of constipated women appears to be somewhat high, and if this be one of the chief causes of neurasthenia, there should be more sufferers from the malady than appears to be the case, assuming the author's deductions to be correct. Another sentence in his paper, the meaning of which we cannot fully grasp, apparently gently hints at the necessary instruction which should be given to young persons, by which they might be enabled to avoid the troubles of constipation. "A special missionary work," he observes, "should be entered into on the part of the profession among teachers of our schools, for they need not only to know the importance of the flushing out of the alimentary canal, so far as they themselves are concerned, but its importance as a stimulator of the wit and the ability of the young idea in the direction of shooting properly!" The meaning of the latter is beyond us, unless we are expected to take it literally. If so, then some information should have been given in respect to the nature of the weapon employed, whether rifle, gun, pop-gun, or pistol. But even then, its connection with constipation would not be very clear. However, in the matter of treatment, the author is more happy. He holds that mothers should be impressed with the fact that children who are poor sleepers run the chance of growing up with wrecked nervous systems. The average mother as well as the average child does not sleep enough. There is much truth in this observation. The child of the present generation is by no means trained in the matter of sleep, as it should be. The noon-day rest for children, so commonly insisted upon by practitioners and parents of former days, is much less adopted as a routine practice than used to be the case, while experience abundantly shows that custom is gradually making the hour later at which children are sent to bed at night. There can be no doubt that in the long run, the diminution or absence of healthy periods of repose for the nervous system in childhood must be concerned as a predisposing cause of neurasthenia. Girls, as well as boys, will be apt, under the system of diminished rest, to grow up with their nervous systems much wanting in stability, and lacking that power which they should possess. In the way of drugs, arsenic is highly spoken of in the treatment of neurasthenic persons, and where insomnia prevails trional, in ten, twenty, or thirty grain doses. The latter remedy can be recommended, inasmuch as no exaltation, no depression, in fact, no bad effects follow its administration. The digestion, moreover, should be assisted by the use of pepsin or papoid.

◆

STATISTICAL REPORT OF THE HEALTH OF THE NAVY.

As usual, the above named blue-book contains much information that is scientifically valuable, a good deal that is useful, and some which is not altogether in accord with current theory of causation of particular diseases referred to therein. Taking the *personnel* of the navy in 1892, numbering 58,330 officers, and seamen of ages varying from 15 to over 45 years, the ratio of total sick and injured at home and abroad was 934·39 per 1,000 strength, being a decrease of 15·6 on the year immediately preceding, and of 62·19 on the previous five years. The ratio of daily sick was 41·69, being a slight decrease as compared with the preceding five years, the average duration of treatment in hospital of each person, 15·25 days. The ratio of deaths, 5·58 per 1,040 in the whole force, was equal to a decrease of ·59 in comparison with 1891, and of 1·23 on the average of the previous five years. On the other hand, the ratio invalided was 26·21 per 1,000, but not more than 17 5 were actually discharged the service, so that the actual loss by medical causes amounted to 23 08.

Considering the nature of duties incidental to ships of war, it is scarcely matter for surprise that wounds and injuries bore a ratio of 184·24 to the strength already given, but the classification which includes together under this head, "heat-stroke, submersion, and asphyxia," surely admits of revision. That the year was one of profound peace is shown by the fact that only seven cases of wounds in action are recorded. These occurred during operations on the river Gambia, and of the number, five proved fatal. But if casualties in battle were few, the expedition alluded to was fertile in cases of malarial fever, showing that the old reputation of "the West Coast" still remains much as it was in years long past, when actual work has to be done on shore. It is noted, however, that the prophylactic power of quinine is doubted by the medical officer in this instance, a circumstance somewhat at variance with past experience.

Malarial fevers occurred in 1,412 cases, of which 13 were fatal, and in 178 the subjects of attack were invalided. The highest number was reported from the West Coast of Africa and Cape of Good Hope Station, namely, 582, these having chiefly occurred among the boat crews employed respectively in the Gambia and oil rivers. Next to that command, that of the Mediterranean furnished the largest number of cases, namely, 15 of ague, and 363 of remittent fever, equal to a total of 378, but it is acknowledged in the report that, "it is often a matter of doubt in which group certain fevers should be included, and among malarial remittent fevers are frequently classed a considerable numbers of cases, the origin of which, in what is usually understood by malaria, is at least questionable." "The more one sees of many cases of the so-called remittent fever, the more one is struck as to its dissimilarity with remittent fever of a purely malarial origin."

Among the men of the fleet on the East India Station, the cases of malarial fever are returned as 121, in China 89, and on the Home Station 99, it being stated with reference to the latter that they were "almost without exception, as far as could be ascertained, recurrences of diseases in subjects who had previously contracted them abroad, especially on the East and West Coasts of Africa, or on the Mediterranean station."

Under the heading of "Simple Continued Fevers" there occurred 1,576 throughout the Fleet, with the happy result that no death took place, and only six men were invalided from this cause. Of "enteric" fever 171 cases are returned, of which number there died 42, and 23 men had to be invalided, equal to 40 per cent. of the former, equal to a combined loss of 37 men. On the Home Station the cases under this head were most numerous, namely, 66, of which there died 15, and were invalided 3. In the Mediterranean command the cases were 49, deaths 19, invalided 13.

Syphilis, both in its primary and secondary form, is shown to have undergone a considerable decrease as compared with the previous year. The incidence of that decrease is given as follows, namely: Home Station, 5·44; Mediterranean, 10·58; North American and West Indian, 5·28; South-East Coast of America, 2·1; Pacific, 14·23; East Indian, 4·71; China, 22·32; Australia, 12·14.

Of what may be called exceptional diseases the sailors of the Fleet had their share, although perhaps to a less extent than the shoregoing population. Thus, epidemic rose rash occurred in 115 cases, of which number 107 were on the Home Station, the great majority having been among the cadets on board the *Brittania*. Influenza occurred in 2,429 cases, with a mortality of 5. The greatest prevalence of the malady so named was on the Home Station, where 827 cases are returned, the deaths above stated being among them. Of other stations named, 141 were on the North American, 156 on the Pacific, 128 on West Coast of Africa, 93 on the East India, 254 on China, and 82 on Australia, thus indicating the vast extent of prevalence geographically of that epidemic.

Medical News.

Royal College of Surgeons of England.

The lecture arrangements for the current term are as follows:—Mr. J. H. Targett will deliver to-day, May 30th, and on June 1st, lectures on "The Pathology of Hydatids in Bone, and of Tumours connected with the Kidney in Children." Prof. Raymond Johnson will deliver on June 4th, 6th, and 8th, three lectures on "Tumours of the Breast." Prof. W. Thorburn will deliver on June 11th, 13th, and 15th, three lectures on "The Surgery of the Spinal cord and its Appendages." And Prof. Pickering Pick will deliver on June 18th, 20th, and 22nd, three lectures on "Diseases of the Ends of the Long Bones in Children." The lectures will commence at 5 o'clock p.m. each day, and all Fellows and members of the College are invited. Gentlemen, not being Fellows or members of the College will be admitted on presentation of their private visiting card at the door of the theatre.

Election of Examiners for the Conjoint Scheme of the Irish College and "Hall."

On Thursday last the Council of the College elected the following Fellows to conduct these examinations:—Anatomy: Dr. Montgomery Ward. Surgery: Mr. Dallas Pratt. Physiology, Histology, and Biology: Dr. G. B. White. Pathology: Dr. Coppinger. Midwifery: Dr. O'Donovan. Ophthalmology: Dr. Odevaine.

Sick Certificates in Law Courts.

In the Dublin Bankruptcy Court, last week, before Judge Boyd, in the case of James Dennis, a bankrupt, a witness who was required for examination sent a medical certificate to the effect that he was unable to attend from illness. Judge Boyd said such certificates were valueless. They should be accompanied by affidavits. The case was adjourned for a week, and in the event of the witness being then unable to attend, it was intimated that an affidavit would have to be filed.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 31, Bombay 36, Madras 33, Paris 22, Brussels 18, Amsterdam 18, Rotterdam 21, The Hague 17, Copenhagen 19, Stockholm 17, Christiania 19, St. Petersburg 23, Moscow 39, Berlin 16, Hamburg 16, Dresden 22, Breslau 24, Munich 22, Vienna 24, Prague 37, Buda-Pesth 27, Trieste 31, Rome 22, Turin 22, Venice —, Cairo 52, Alexandria 37, New York 20, Brooklyn 21, Philadelphia 18, New Orleans 23.

Vital Statistics.

The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 17·1 per 1,000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year, and were—Birkenhead 18, Birmingham 18, Blackburn 16, Bolton 15, Bradford 18, Brighton 16, Bristol 14, Burnley 16, Cardiff 17, Croydon 7, Derby 12, Dublin 25, Edinburgh 18, Gateshead 15, Glasgow 17, Halifax 15, Huddersfield 16, Hull 15, Leeds 16, Leicester 13, Liverpool 21, London 17, Manchester 17, Newcastle-on-Tyne 16, Norwich 22, Nottingham 20, Oldham 14, Plymouth 16, Portsmouth 9, Preston 14, Salford 21, Sheffield 14, Sunderland 13, Swansea 15, West Ham 15, Wolverhampton 20. The highest annual death-rates were—From measles, 2·2 in Halifax, 2·3 in Nottingham, and 2·5 in Birmingham; from whooping-cough, 1·4 in Cardiff and 1·8 in Plymouth; and from diarrhœa, 1·0 in Norwich. The death-rates from scarlet fever and fever did not reach 1·0 per 1,000 in any of the towns.

Health of Dublin.

According to the report of Sir C. Cameron, Superintendent Medical Officer of Health, for the month of April, the death-rate was lower than in any corresponding period during the previous 10 years, with the exception of April, 1890, and was 4·21 per 1,000 below the mean rate. As compared with the previous month the deaths from influenza declined nearly one-half. As to the other principal zymotic diseases there were very trifling differences between the months.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MR. C H S.—We are unable to devote further space to a discussion of the subject.

DR. CRAIG.—We hope to have space for your paper on "Grave's Disease" in our next.

MR. STEPHEN PAGET'S Post Graduate Lecture on "Otorrhœa and its Dangers" is marked for early insertion.

DR. THUDICHUM.—The illustrations have been put in hand, and your paper will appear as soon as these are ready.

A NEW EXPRESSION FOR VACCINE.

A RABID anti-vaccinationist in a public meeting at Birmingham last week, described vaccine, as "the cult of the rotten calf"!!! This entirely original conception is worthy of being recorded.

PATHOLOGY *IN NUBIBUS.*

THUS writes a correspondent to a contemporary: "The skull of a man who has died from delirium tremens contains an alcoholic gas. A small opening in the skull, soon after death. permits this gas to escape, and it can be ignited, and burns with a bluish flame." And so the knowledge of the things in this world grows!

ILLEGAL ASSUMPTION OF TITLES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Can a man, whose name has been removed from the "Medical Register," continue to practise, write, or print the letters of his diploma after his name, and run an "hygienic hospital"?

If he can, what is the good of registration? If he cannot, why is he allowed to do so, to the detriment of registered men and the public?

Surely some steps could be taken to rid London and the provinces of such pests.

I am, yours, &c.,
C. S.

⁂ [He cannot legally use the diplomas of which he has been deprived. The law, if set in motion, could immediately stop the practice.—ED.

POOR-LAW ATTENDANCE.

MC. K. writes:—A patient (red ticket) lives in the townland of "a" which is in "A's" district, but somehow the house in which the patient lives is rated for the townland of "b," which is in "B's" district, now which is bound to attend him?

⁂ [The doctor in whose district the patient is geographically situated, must attend, no matter where the residence is rated. But, probably, there is a mistake, which can be readily corrected.—ED.]

F. R. C. (Wandsworth).—Our correspondent can obtain a supply of oxygen gas ready for inhalation of Messrs. Krohne & Sesemann, Duke Street, Manchester Square, W.

MESSRS. K. & M.—You can obtain the address of any registered practitioner at the offices of the General Medical Council, 299 Oxford Street, W., without charge. Should the registered address fail to find the practitioner his name would be removed from the official Register.

Meetings of Societies, Lectures, &c.

WEDNESDAY, MAY 30TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—At 4 p.m, Introductory Address by Dr. Pye-Smith. 4.30 p.m., Exhibition of Cases.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Pemphigus and its Allies.

METROPOLITAN HOSPITAL (Kingsland Road, N.E.).—At 5 p.m., Dr. Gow: The Surgical Aspect of Tubal Disease. (Post-Graduate Lecture.)

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p m., Mr. James Henry Targett: Hydatids in Bone. (Second Erasmus Wilson Lecture.)

THURSDAY, MAY 31ST.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—At 5 p.m., Dr. Byrom Bramwell: Thyroid Feeding in Diseases of the Skin. 9 p.m., Annual Meeting and Conversazione.

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond Street.—At 3 30 p.m, Dr. Barlow: Clinical Lecture.—National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Beevor: Muscular Atrophy.—Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Dr. Pye-Smith: Cases in the Wards.

FRIDAY, JUNE 1ST.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital)—At 8 p.m., Clinical Meeting. Dr. Scanes Spicer: Case Illustrating the Radical Cure of Fetid Suppuration of the Nose by Free Opening, Curettement, and Drainage of Maxillary Antrum.—Mr. McAdam Eccles: (1) Case of probable Deposit of Urate of Soda in the Scrotum; (2) Case of Multiple Tumours of the Abdominal Wall. Mr. T. R. Atkinson: Case of Multiple Lipomata.—Mr. L. A. Bidwell: (1) Congenital Tumour over Sacrum; (2) Syphilitic Disease of Humerus which caused Spontaneous Fracture.—Dr. Morgan Dockrell: (1) Rodent Ulcer of Twenty Years' Duration treated with Resorcin; (2) Case of Mycosis Fungoides.—Dr. Abraham: Cases of Skin Disease.

LONDON HOSPITAL MEDICAL COLLEGE.—At 4 p.m., Mr. Jonathan Hutchinson: On Family Diseases.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Mr. James Henry Targett: Tumours of Kidney in Children. (Third Erasmus Wilson Lecture.)

SATURDAY, JUNE 2ND.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital.—At 11 a.m, Dr. Hyslop: Climacteric and Senile Insanity.

MONDAY, JUNE 4TH.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Syphilides.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—At 8 p.m., Mr. Edmund Owen: The Treatment of Carious Milk Molars. Casual Communications: Mr. S. A. Coxon: The Adjustment of Spinal Springs.—Mr. D. G. Ronthop will show a Low Voltage Motor.

Vacancies.

Armagh Union.—Loughgall Dispensary.—Medical Officer. Salary £120 per annum, with fees, and £20 per annum as Medical Officer of Health. Election June 11th.

Bridgwater Infirmary.—House Surgeon. Salary £70 per annum, with board and residence. Applications and testimonials to the Hon. Secretary on or before June 15th.

Flintshire Dispensary.—Resident House Surgeon. Salary £120 per annum, with furnished house, &c Applications and testimonials to the Secretary on or before June 5th.

Glasgow Eye Infirmary.—Resident Assistant House Surgeon. Salary £50 per annum, with apartments and board. Applications and testimonials so the Secretary on or before June 11th.

Gorey Union.—Medical Officer. Salary £100 per annum, and £20 per annum as Consulting Sanitary Officer. Election June 9th.

Jaffray Suburban Branch of the General Hospital, Gravelly Hill, near Birmingham.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing. Applications and testimonials to the House Governor on or before May 29th.

Royal Berks Hospital.—Assistant House Surgeon. No salary, but board and lodging will be provided. Applications and testimonials to the Secretary on or before June 12th.

Worcester General Infirmary.—Assistant House Surgeon and Dispenser (unmarried). Salary £70 per annum, with board, residence, and washing. Applications and testimonials to the Secretary on or before June 2nd.

Appointments

CARDINALL, C. D., M.R.C.S., L.R.C.P., L.S.A., Senior House Surgeon to the Western General Dispensary.

COULSON, J. E., M.R.C.S., L.R.C.P., Junior Assistant Medical Officer at St. George's Infirmary, Fulham.

GUILDING, L. M., M.B., B.Ch.Oxon., M.R.C.S., Medical Officer for the Workhouse, Reading.

KENDALL, N. F., M.R.C.S.Eng., L.R.C.P.Lond., Assistant Resident Medical Officer to Woolwich Infirmary.

MCAVOY, H., L.R.C.S.I., L.K.Q.C.P.I., L.M.Rotunda, Junior House Surgeon to the Jervis Street Hospital, Dublin.

MCCOMISKEY, A. W. S., M.B, B.Ch., L.R.C.P., L.M., L.R.C.S.I., Medical Officer for the Killough Dispensary District

MCDOUGALL, A. H., L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer for the Crumpsall Workhouse, Manchester.

MOYNIHAN, J. J., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Medical Officer for the Baltinspittle Dispensary District.

O'CONNOR, J. E., M.B., B.S.Irel., Medical Officer for the Glenfield Sanitary District of the Blaby Union.

ROBERTS, E., M.R.C.S., Surgeon to the Manchester Royal Eye Hospital.

ROOCROFT, W., M.R.C.S., Honorary Consulting Surgeon to the Royal Albert Edward Infirmary, Wigan.

SHAW, R. F., L.R.C.P., L.R.C.S., L.M.Ed., L.F.P.S.Glasg., Medical Officer for the Kirburton Sanitary District, Huddersfield.

SHEPHERD, C. D., M.R.C.S., Honorary Consulting Surgeon to the Royal Albert Edward Infirmary, Wigan.

TATTERSALL C. H., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Oldham Urban Sanitary District of the Oldham Union.

WEEKES, H. H., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Gillingham Sanitary District of the Medway Union

Births.

HARDING.—May 20th, at Sandgate, the wife of Surgeon-Major A. Harding, A.M.S., of a daughter.

WIGMORE.—May 25th, at 39 Compayne Gardens, S. Hampstead, the wife of Arthur W. Wigmore, L.R.C.P.Lond., of a son.

Deaths.

LEMON.—May 25th, at 12 Highbury Grange, London, Oliver Lemon, M.R.C.S., late of Kings Langley, aged 74.

M'CORMACK.—May 19th, at Felling-on-Tyne, Durham, Dr. Laurence M'Cormack, aged 40.

REECE.—May 20th, suddenly, Richard Reece, M.R.C.S., of Walton on-Thames, aged 85.

WARNEFORD-THOMSON.—May 15th, at Merriott, Somerset, Herbert Warneford-Thomson, L.R.C.P., formerly of Queen's Road, Brownswood Park, N., aged 43.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

Original Communications.

ABOUT SOME THERAPEUTIC OMISSIONS IN TEXT-BOOKS ON DISEASES OF THE SKIN.

By JOHN KENT SPENDER, M.D.Lond.,
Lately Physician to the Royal Mineral Water Hospital, Bath.

WHEN text-books in special departments of medicine reach the bulk of nearly a thousand pages, the members of a laborious profession begin to protest and cry aloud! Even those who have a strong literary appetite and digestion feel frightened. Conscience tells them that they ought to know everything, and this is becoming every year more impossible. But there are many men who have time to read only a very little, and that little ought to be gathered into a brief and practical form.

Now, concerning organs and structures which lie on the outside of the body, there are few things which bring more credit to the general practitioner, especially in small country towns, than the right diagnosis and prompt treatment of the commoner diseases of the skin. The total neglect of clinical teaching in these matters was a reproach to our medical schools up to about thirty years ago. The danger is now that there may be too much teaching and too little learned. But teachers and learners will be in better temper with each other if there be a mutual understanding about the knowledge which is necessary, and the knowledge which is only ornamental.

At the end of a little book written by the late Dr. Hughes Bennett more than forty years ago there are twelve pages devoted to the Classification and Diagnosis of Cutaneous Diseases. Twelve pages! But this tiny breviary was of great use to many practitioners who were "qualified" in a legal sense, but had never received an hour's instruction about certain common maladies which are more ugly than dangerous. The subject was handled on firmer and broader lines in the "Principles and Practice of Medicine," a third edition of which was published by Dr. Bennett in 1859. For thirteen or fourteen years afterwards diseases of the skin were regarded in this country mainly as a final chapter in "Systems of Surgery" and "Systems of Medicine." The encyclopædic style and size of the new literary form of cutaneous diseases dates from about twenty years ago.

There are two great merits in all our important handbooks. One is that the pathological histology of diseases of the skin is plainly described and sometimes admirably illustrated. The other merit of these books is that they always contain a sufficient description of the rarer lesions which occur to a medical man only once or twice in his life, and are, therefore, apt to be forgotten or misunderstood. But, on the other hand, why may not these curiosities be relegated to the modest seclusion of small print and quiet chapters? This seclusion would be a relief to the eye, and a harbour of refuge for the mind. Things of minor importance would no longer distract the attention. Adequate thought and time might then be bestowed upon those fundamental points of pathology and treatment, ignorance of which disentitles a man for ever from being a cutaneous therapeutist.

It is not to be denied that there are serious hindrances to a rational therapeusis of the skin. A number of reputed remedies are purely empirical and rest upon no obvious logical basis. Trustworthy medicines, external and internal, are too often set aside for new things of doubtful origin and lineage. Foreign experience is allowed a disproportionate weight in determining the lines of English practice. A parade of authorities looks erudite; but, as a matter of fact, the application of foreign rules and methods has to be guarded by many limitations. Thus, we are drily assured by one English writer that few patients will submit to a plan (specially described) which is not only tedious but increases the disfigurement for the time being. Then what is the necessity for discussing the plan? We are indebted to Hebra and Kaposi for philosophic grasp of view, but their remedies are often greatly unsuited to the delicate skin of the Anglo-Saxon race. Unna's pharmacopœia is more in touch with Great Britain. An odd point of the Vienna treatment is that sometimes the strongest form of a medicine is tried first, and this is gradually softened down to the mildest. We will be lenient here, and say nothing about the repulsive ill-smelling things which have their chief haunt and home across the Channel.

An encyclopædic author should learn to communicate his knowledge in the form which most quickly engages the attention. All experts are encyclopædists within their own range, but not all their knowledge is equally valuable. The formula of a catechism (much loved by Mr. Jonathan Hutchinson) assumes, perhaps, that the reader is always a student; in four cases out of five he seeks learning only for the sake of curing someone, and not for the learning's sake itself. Imagine now, that the expert desires to teach us how to treat a common and rather polymorphic disease, psoriasis. He should trace in firm and clear outlines the method of treatment which he has found most prompt and (in the long run) most successful. Emphasis should be laid on that method as best adapted for the ordinary forms of psoriasis as seen on the outside of the limbs, and on the homologous surfaces of elbow and knee. But what is to be done with two kindred types of disease which are fairly common, but (unfortunately) far less tractable?:—(*a*) The dark circumscribed almost non-scaly patches which affect chiefly the lower parts of the back; and (*b*) the soft patches which are like eczema in appearance and situation and mode of spreading? Here are something like three distinct diseases, requiring three distinct therapeutic attitudes. One rigid formula of "psoriasis" cannot cover the whole therapeutic ground.

The external application of tar was recommended in all the older text-books as supreme for the common *psoriasis diffusa* of the outer surface of the limbs. Now here is a remedy which is splendid if used properly, and a poison if used wrongly. The good traditions of tar are still upheld, but there is a singular lack of instruction as to the right mode of preparing it. The *unguentum picis liquidæ* irritates and inflames, even when largely diluted with lanolin or vaseline. Nor are matters any better if the tar ointment be mixed with benzoated lard, spermaceti, or any similar thing.

The suitable diluent of tar—the one chemical medium which neutralises all its evil, and augments all its power for good—is an alkaline earth like chalk. The chalk must not be merely rubbed down with the tar by the rough mechanism of a spatula, but a regular chalk ointment ought to be first made by strewing chalk into melted lard, and then stirring the two until they are thick and cold. If a finely levigated chalk be used, a bland product is the result, which can be combined with *unguentum picis liquidæ* in any proportion that the case seems to demand.

Here, then, is the therapeutic secret of tar. The emollient qualities of chalk (to which bismuth may be added) are beneficial in allaying pruritus, and in helping to arrest the neoplastic tendency of the scaly order of skin diseases. The percentage of tar ointment to chalk ointment may begin with one part in eight. After a bath at bedtime, the warm and moistened skin should be smeared with the ointment just described, and a vest put on over it. The objections to the smell of tar are conjectural and imaginary: a wholesome and antiseptic odour will not disgust rational patients, whose philosophic boast often is that they can "take anything."

The chrysophanic plaister mull as an application to the hard mahogany patches of scaly disease on the back and outside of the lower limbs, is not mentioned in one of the biggest of English handbooks. Here was once the despair of the dermatologist; but the doubtful panacea of sulphur waters has been superseded by Unna's ingenuity. If my own experience be accepted as in any way a guide, it is strongly in favour of a remedy so simple and so clean.

The management of those patches of psoriasis which are like eczema in distribution and behaviour, is an important chapter of practical therapeutics. The essential point to remember is that this clinical form is liable to *spread suddenly and become an exfoliative dermatitis*. The psoriasis is the germ of an exudation into lymph-spaces and connective tissue: and if a crop of satellites appear around the main patches, extending to the palms of the hands or the soles of the feet, the danger is great. At this stage of matters we discard all academic terminology, and look at the complaint as if it were a spreading erythema or even an erysipelas.

When such a case occurs among patients sent to Bath for thermal treatment, we suspend the use of waters, and order a person to bed. Rest of the whole system; an equalisation of blood-pressure; an uniform temperature; and a rigidly moderate diet with abstinence from alcohol—these are the elementary postulates of what we have to do. Externally I apply almost constantly one of two things: (*a*) a combination of sweet almond oil and vaseline, or (*b*) a combination of oxide of zinc, calamine, sweet almond oil, and lime water. Both are very soothing, and help to quiet the vaso-motor storm.

There is only one internal medicine of the slightest utility, and that is tartrate of antimony. But all depends upon the vigour and perseverance of its administration. If prescribed in the penurious and timid doles recommended by some authors, it is simply powerless for good or harm. "Be not afraid of power" was the maxim of a medical philosopher who knew that the biggest engine can do the finest work, if properly handled. Give 15 minims of antimonial wine (abundantly diluted) every two hours from 7 in the morning until 11 at night, and in a large proportion of cases there is not only no disturbance of gastric or intestinal function, but a quick arrest of the disease. Sometimes this dosage can be begun every hour, and continued for half a day; very seldom is it that five doses during the day hours cannot be well borne, if the diet be limited and absolute repose in bed enjoined. And the result of this medication is often very striking. The raging tumult of skin-structures subsides; the margin of redness ceases to extend; and paleness is observed in the centre of the purple fire. Withdraw the antimony by degrees: for several weeks it should be taken at least twice a day as a decided vaso-motor tonic. This is the standpoint from which Dr. Billing and some of his contemporaries 40 years ago regarded tartrate of antimony, after its so-called antiphlogistic influence has spent itself.

When exfoliative dermatitis (beginning as apparent psoriasis) has once become established over a large area of the body, it may be "tamed down" and kept quiet by rigorous hygienic care. But there it is, and for a while it is like a smouldering prairie. Anything may stir the glowing embers. And now we may prescribe perchloride of mercury (with or without chlorate of potash), perhaps guided by the old romance of its "alterative" virtues; but this matters little. What we know for certain is, that this now little-used medicine modifies nutrition, so that textures are renewed in a more solid way and with more durable plastic force. Cod-liver oil is always a valuable auxiliary.

A negative precept in medicine has to be repeated sometimes with unwonted vigour. It cannot be said too often that arsenic in any form or combination is a poison to exfoliative dermatitis, especially when any increasing patch of it is surrounded with "satellites" which go up into the hand and creep around the foot.

One more therapeutic oversight in Text-Books of Skin Diseases ought to be mentioned. A swollen leg afflicted with *eczema rubrum* or *madidans* from knee to ankle: how ought it to be treated? Well, there are three ways in which it ought not to be treated, and these are as follows:—No ointment must be applied; no dry powder should be dusted over it; and a gelatine varnish is the most intolerable of all.

More than 30 years ago I discovered that the ordinary black wash (*Lotio Hydrargyri nigra* of P.B.) is successful and curative in a remarkable degree. Dilute it with a twelfth part by measure of glycerine, and pour a small quantity into a soap-dish or saucer. Soak strips of linen rag in the lotion, taking up on each strip as much as possible of the black oxide of mercury. Lay them evenly upon the limb, each overlapping the next by about the eighth of an inch. Cover the whole diseased surface this way, and retain the dressing in its place by a thin cheesecloth bandage. Everything must be renewed twice-a-day, and the strips of linen ought to be soaked before removal in warm water. Nothing can answer better than this simple plan; but (so far as I know) no dermatologist of repute describes and sanctions it with the exception of Dr. Purdon, of Belfast, and his testimony to its value has been again confirmed in a recent number of the *Dublin Journal of Medical Science*.

Passing over several points of less moment, I conclude with a short note upon the therapeutic effect of mineral waters. It is declared by a high authority that our natural medicated waters are locally not more effective than equally long immersions at home. It is difficult to prove or to disprove a statement of this kind. But we may at least claim for our own hot springs that provision is made in our baths for bulk of water, for maintaining an even temperature during any length of time, and for "packing" the patient afterwards with suitable wrappings. These mechanical aids make the application of the Bath waters an easy task. In the medical literature of the Eighteenth century there are many records of the successful treatment of "leprous eruptions" by the thermal waters of Bath, which are, in a chemical sense, a hot alkaline lotion. No scientific physician considers this "lotion" to have any specific virtue; but the physical convenience and comfort which attend the administration of our waters confer on them a healing power, which need not be associated with mystery or empiricism.

◆

CHRONIC OVARITIS, ITS ORIGIN AND TREATMENT.

By W. J. BURLEIGH-ROBINSON, M.D.Durh.

By chronic ovaritis, the title which heads this article, I wish to express the result of that slow and insidious process of inflammation which occurs in weakly women and strumous subjects, and not the better understood chronic interstitial ovaritis, the result of specific infection and direct continuity of external inflammation. "Winternitz," in the *Centralblatt für Gynakologie*, enumerates the causes of chronic oophorites as follows:—

1. Injuries during menstruation.
2. Puerperal troubles.
3. Gonorrhœa.
4. Masturbation.
5. Infection, due to external poisons.

Leaving out gonorrhœa, take the above causes as those of that form of chronic ovaritis, of which I would treat, and to them I add leucorrhœa. In the great majority of cases, patients do not consult us until such time as they complain of pain, constant in character in one definite spot in the abdomen, a feeling of a lump, and a sensation as of something dragging and burning. It then becomes of the utmost importance to inquire into the previous history which is usually as follows:—

Patient has been always "delicate," not necessarily ill, but that vague debility requiring cod-liver oil at an early age, and good living.

2. The menstrual history is irregular.

3. There may or may not have been early dysmenorrhœa.

4. The irregularity in menstruating is shortly followed by the appearance of a discharge—leucorrhæa—and it is from the date of the appearance of this discharge that the process producing chronic ovaritis may be said to start.

We know that increased function in the vagina will produce function and growth in the mammæ, uterus, and ovary, and the leucorrhœa by its mere presence, possessing as it does, the three attributes, heat, moisture, filth, will supply all the requirements for infection by septic organisms, the patient thus being laid open to the chance of constantly recurring though slight attacks of more or less septic vaginitis. Again, the chronicity and neglect of leucorrhœa is proverbial, and I have no doubt that a long-continued disordered function, such as this discharge, will result in chronic changes in the ovaries, which, slight in themselves, place these organs at a great disadvantage from the point of view of recovery, should they at any time become the seat of any acute or subacute affection.

It is thus of the utmost importance that with the appearance of the discharge treatment should begin, and *not* as is so often the case, the young patient left alone under the prevailing idea that "as she gets older she will grow out of it."

With the exception of the discharge which most English women persistently ignore, no symptoms of any note occur until such time as through cold, damp, or puerperal troubles, an acute inflammation attacks the already chronically diseased ovary, then we get pain, fever, rigors, and in fact, all the symptoms of acute pelvic cellulitis followed by months of pain and discomfort.

It is at this time we are generally consulted, and then we find the great importance of inquiring closely into the previous history, to prevent "a mistake in diagnosis."

Treatment.—Whenever possible it is the duty of the practitioner to ascertain whether his patient suffers from a discharge, and if so, to ascertain its cause and source. Should it be leucorrhœa, tonics, cod-liver oil, and nutritious diet must be given, together with injections of dilute boracic acid daily. Then, with fresh air—especially country air—from green fields, a recovery will probably ensue.

Should the symptom be due to a cervicitis, and the discharge be seen issuing from the os, great care must be taken in attacking it, for often the ovary has become irritated at the same time the cervicitis developed, and any free interference with suppositories, sounds or curette, is liable to and frequently does produce an acutes ovaritis of a dangerous character. In the latter stages when chronicity is apparent, local anæsthesia should be applied to the abdomen. Leeches will be found useful as an occasional blister. But it is principally essential that as much new blood as possible should be sent to the ovaries, and to aid this ferruginous tonics should be administered. The patient should also rest on an inclined plane, the pelvis being raised at an angle of about 15 degrees, thus relaxing the broad ligament and allowing of a freer circulation. The disease is a chronic one, the treatment must necessarily be prolonged, and, in fact, the bedstead of a woman suffering from chronic ovaritis should *never* be allowed to assume the level plane. Gentle exercise, such as an hour or two in a bath chair daily, or carriage drive, when the jolting can be borne, is beneficial; the diet should be nourishing, and alcohol in any form is directly contra-indicated owing to the great probability of the habit being formed.

This treatment followed out thoroughly will give great relief, though slight relapses occur.

The formidable operation of removing the ovaries should be our very last step in treatment, for owing to the numerous adhesions around the organs it is often extremely difficult and dangerous. In fact, the operation should never be undertaken unless we see that all other efforts have failed, and that the patient's nerve force and strength is being worn away, or we have reason to suspect pus in the vicinity.

The wholesale "spaying" of women which of recent years has become so fashionable, is most serious in its results as to marital happiness, and dangerous to life, and excepting where life is in danger absolutely unscientific.

◆

AN UNUSUAL CASE OF GRAVES' DISEASE. (a)

By JAMES CRAIG, M.D., Univ. Dub., F.R.C.P.I.,

Physician to the Meath Hospital and Co. Dublin Infirmary.

The patient is a girl, who came under my care in the Meath Hospital on May 4th, 1893. She was æt. 25, unmarried, and had been in employment as a general domestic servant until December, 1892. During the summer of that year she had suffered from anæmia and palpitations and had noticed her neck becoming enlarged. Then in November menstruation ceased, and after a month of severe frontal neuralgia, the eyes became prominent. There was no history of fright or mental emotion, nor of any family neuroses. In January, 1893, she went to the South Dublin Union Hospital, where she fretted much, and after a time found her eyes become red and painful and very prominent. When she came under my care in the month of May her eyes were in a most alarming condition, of which the drawing and photograph give only a very imperfect picture. The eyeballs were markedly prominent, and the lower half of the bulbar and palpebral conjunctiva of each eye formed a red protruding mass which buried the edge of the lower lids completely beneath it. The lower portion of each cornea was ulcerated, there was no anterior chamber, and in the right eye a small mass, which appeared to be the lens, lay on the swollen tissues. The upper lids were freely movable, and the conjunctiva underneath was red and congested, but free from chemosis. The sight was gone, except that she could distinguish light from darkness. Pain was so intense that she had not slept at all for nearly a week previous.

(a) Read before the Royal Academy of Medicine, May 11th, 1894.

With regard to other symptoms, her pulse varied at short intervals from 120 to 170 per minute. The heart was weak, irregular, slightly enlarged, and with a pulmonary systolic murmur. The thyroid enlargement was not great, but was symmetrical, and about the size of a small orange on either side, while pulsation and bruit in it were distinct. She was very nervous and excitable, and her hands and arms especially showed a constant tremor. She had suffered before admission from an exhausting diarrhœa, and complained of being weak and tired. The body was emaciated, and the mammary glands atrophied. The chest movements were much restricted during respiration, a symptom which has been lately pointed out by Bryson of New York. She perspired freely from slight causes, and her skin always felt hot. The urine contained a trace of sugar but no albumen. The skin was not pigmented, except on the upper lids, and the appetite was small on admission, although afterwards it became voracious.

The condition of the eyes, however, was the special feature of the case, and one which called for immediate relief. Dr. Johnston kindly saw her with me, and divided the outer canthus of each eye with a pair of scissors, then on the following morning he made several incisions in the swollen mass of each eye by transfixing it with a narrow cataract knife from the corneal margin to the edge of the lower lid. The bleeding which followed considerably reduced the swelling, and as division of the canthi had allowed the eyeballs to protrude still further, the patient was so much relieved that she slept well that night. The remainder of the treatment consisted in the application of warm boracic lotion, and subsequently the globe was covered by gold beater's skin on which a little boracic ointment was spread. There was no active spreading ulceration of the cornea, and Dr. Johnston thought the ulceration was partly due to exposure and partly perhaps to pressure, although it was difficult to understand how the latter could act on the nourishment, nervous or otherwise, of only one half of the cornea. His idea in carrying out this line of treatment was that he would reduce the pressure on the globe, cause the eye to retract, and above all make the patient more comfortable. He also feared if the eyes were left in the state of congestion or strangulation which was present that panophthalmitis would set in. The result was satisfactory in so far as it averted destruction of all the tissues of the eye and gave relief to the girl, but although the swelling somewhat diminished at the time, and acute symptoms subsided, the ulceration extended to the upper part of the cornea, and as the sight did not return, and the swollen red mass still persists to some extent, at the end of a year it has been found necessary to place the girl in an asylum for the blind.

In the records of the numerous cases which I have examined I can find no evidence that any eye complication so serious as this has ever before been observed.

Gowers says, "When the lids fail to cover the eyes these are often dry in the morning. Corneal inflammation is sometimes met with, apparently due to imperfect protection of the globe when the lids fail to meet, conjunctivitis is not rare, and occasionally there has been opacity of the cornea and even sloughing, generally in both eyes, but in one before the other. Œdema of the lids is occasionally present, and may be associated with œdema of the conjunctiva." And Mr. Swanzy, in his "Handbook on the Eye," says "the sensibility of the cornea is lessened. Ulcers of the cornea are not common, but are more often seen in men than in women. The exposure of the eye and the dryness of the cornea are probably to a great extent the cause of ulceration when it occurs, but Sattler inclines to the belief that it is also largely due to paralysis of the nervous supply of the cornea."

In a paper by Dianoux on "The Ocular Lesions in Exophthalmic Goître," read before the International Medical Congress in 1886, he considers that stretching of the ciliary and optic nerves by the exophthalmos produces the internal eye lesions, which he classes under three heads—(1) the effects on motor organs, viz., dilatation of the pupil and paralysis of accommodation; (2) the effects on nutrition, viz., neuro-paralytic corneitis, papillary œdema, and irido-choroiditis; and (3) the effects on sight, viz., mist, shimmering, and finally amblyopia.

While I have gone so fully into eye complications in this affection, it may be well to mention in detail the more commonly observed ocular phenomena:—1. Exophthalmos, which is present in about 90 per cent. of the cases, and which may be unilateral or bilateral, or more marked on one side than the other, and which varies in degree according to the heart action. 2. Graefe's lid sign, or impairment of the consensual movement of the upper eyelid in association with the eyeball on the patient looking downwards, and a modification of this has been noticed by Ramsay in the form of a spasmodic retraction of the upper lid after an imperfect descent. 3. Stellwag's sign, which consists in an incompleteness and diminished frequency of the involuntary act of winking. 4. Dalrymple's sign, or abnormal widening of the palpebral orifice which is due to retraction of the upper lid. Very rarely the lower lid had been retracted also. 5. Möbius and others have recorded paresis of the muscles that move the eyeball, and even complete ophthalmoplegia has been noted. Finally, tremor of the lids and tremor of the eyeballs have both been noticed, the former of no significance, as it occurs in people in health, the latter a nystagmus which probably corresponds to the tremor of the body and limbs.

In this case of my own there was no secretion or appearance of acute inflammation, but the condition resembled rather that seen in the case of strangulated hæmorrhoids. And although there is some obscurity as to the cause of this serious complication and as to its method of onset, we have at all events learned this lesson, that in all cases of Graves' disease where the exophthalmos prevents the lids from meeting over the eyeballs every precaution should be adopted by the medical attendant to lessen the corneal exposure and reduce the proptosis. The methods that have been found useful for these purposes are tightly applied muslin bandages over the eyes, the application of tincture of iodine to the upper lids and where the protrusion is very great, the eyelids should be stitched together, or even in order to lessen the palpebral orifice the upper and lower lids should be united in the region of both commissures by vivifying their edges for some distance and stitching them together so as to bring about a permanent union. However, it is only right to mention that a young girl who was undergoing an operation of this sort died suddenly on the operating table in Guy's Hospital in June, 1873, but this untoward result may not be taken to prove more than that a tendency to sudden death exists in exophthalmic goître.

Since the three cardinal symptoms of this affection were first grouped together by Graves as a separate and definite malady, many additional symptoms have been described, some of which, like tremor, are almost constantly present, while others are found with more or less varying frequency. Most of these have been mentioned by Dr. Foot in his particularly interesting and instructive lecture on this affection, which appears in the second series of International Clinics. He there also calls attention to the undoubted right of associating with this malady the name of its discoverer Graves, rather than that of Basedow. So that it is interesting to find in the most recently published German treatise on exophthalmic goitre an admission by the author, Dr. Mannheim, of Berlin, that in studying the history of the affection, he discovered that Graves had known, recognised and described the disease before Basedow, and that therefore one could not refuse to give him the priority and name the disease after him, and this he adopts as the title of his work, "Morbus Gravesii."

I could not attempt within the space of a short paper to discuss fully the various theories that have been put forward with regard to the pathology of this perplexing disease. But while it is almost universally accepted by writers on diseases of the nervous system, and by pathologists generally, that the symptoms owe their origin to a functional or organic lesion of the central nervous system, there are at the present day not a few who, following on the lines of Möbius, consider that the starting-point in the affection is the altered condition of the thyroid gland, which either by a hypersecretion or altered secretion disposes of toxic agents to the blood, which in turn produce minute pathological changes, or it may be only functional disturbances in the central nervous system. This latter view has lately received more attention on account of the recent researches that have been made in regard to the functions of the thyroid gland, but more chiefly in regard to its atrophied state in producing the condition known as myxœdema, and to the highly successful result of treating this latter disease with some preparation of the gland itself.

In the first place I would mention briefly that Mr. Victor Horsley's researches have gone to prove the importance of the thyroid as a blood forming and metabolic agent. He says it forms or rather secretes from the blood a colloidal substance which is transmitted by the lymphatics from the acini of the gland back to the circulation, and it is of special metabolic importance in early extra-uterine life, as shown by the more fatal effect of thyroidectomy in young animals, while its value falls as the general vital processes decrease. Its great importance in relation to health is shown by the effects that follow its removal in animals; these are (1) diminution in the corpuscular elements of the blood, and in the amount of its oxygen, with the presence of abnormal constituents in the plasma such as mucin; (2) a general toxæmic state which gives rise to excitatory and subsequently paralytic changes in the central nervous system, which are shown by tremors, spasms, rigidity, and afterwards motor and sensory paralysis; and in the third place derangement of nutrition follows, as shown by emaciation, increase of mucin in the subcutaneous tissues and even later fibroid increase, with heat changes, also, in which the temperature is first above and afterwards below normal, and in which the symptoms are aggravated by cold and ameliorated by heat.

So much therefore for the importance of this gland in the preservation of the economy of the body.

Undoubtedly there is an increase or perversion of its functions in Graves' disease, which one might readily assume to be the cause of many of the secondary symptoms, but those who support the view, among whom are Professor Greenfield and Dr. Byrom Bramwell of Edinburgh, that the primary source of the malady has its origin in the altered state of the gland, reason from the following data:—

(1) The pathological state of the thyroid in ex. goitre.

(2) The presence in the nervous system—particularly in that part of it which from the symptoms one would suspect to be involved—of slight but widespread changes which are of a like nature to those seen in toxic diseases, such as hydrophobia and tetanus, and therefore suggesting that these changes in Graves' disease may also be of toxic origin.

(3) A comparison of the clinical features of myxœdema in which the gland is atrophied with those of ex. goitre in which it is enlarged.

(4) The beneficial effects on this disease of partial thyroidectomy.

(5) The beneficial effects which follow medical treatment directed to reducing the size of the goitre.

(6) The correspondence in some important respects of the phenomena of Graves' disease with those produced by artificial introduction of the thyroid secretion.

With regard to its pathological structure, Drs. Grainger Stewart and Gibson reported at the British Medical Association last August the result of postmortem examinations which had been made in three cases, and Professor Greenfield in the "Bradshaw Lecture," delivered before the Royal College of Physicians last November, recorded the result of his observations on six fatal cases. In every instance there was marked increase in the secreting structure of the gland, which Professor Greenfield considered bore the same relation to the normal gland as that which the mammary gland in lactation bears to itself when in a state of quiescence, and in peculiar contrast to what has generally been accepted the gland was found to be not very vascular, at least the increase in vascularity was not more than is met with in a secreting mammary gland. Greenfield points out that great increase in the secreting tissue and greatly exaggerated function may be present without notable increase in volume. In advanced stages of the disease fibrous overgrowth may replace the secreting structure, and in that case one might expect a subsidence of the symptoms, or even if the glandular atrophy is extreme myxœdema may ensue—a sequela which it is true has been sometimes observed.

Coming to the next point in the argument, although the changes found in the nervous system are not by any means constant, still minute hæmorrhages and degenerative changes are frequently met with which closely resemble the conditions that are observed in diseases like tetanus and hydrophobia which are believed to be of toxæmic origin.

In contrasting the clinical features of myxœdema with those of Graves' disease the following points are called attention to:—

In Ex. Goitre.

1. The gland is hypertrophied.
2. Young women are affected.
3. There is hyper-excitability, nervousness, tremors, and unrest.
4. The skin is soft, smooth, moist, with excessive perspiration and diminished electrical resistance.
5. There are subjective sensations of heat (flushing), with easily produced elevations of temperature.
6. The pulse is frequent.
7. There is marked emaciation.
8. Amenorrhœa is common.
9. Marriage and pregnancy may cure.
10. Mental disorder more usually take the form of acute mania.

In Myxœdema.

1. It is atrophied.
2. Older women suffer.
3. The patient is stolid and placid.
4. The skin is dry, harsh, rough, no sweating, and increased electrical resistance.
5. There is feeling of coldness with subnormal and unvarying temperature.
6. It is slow or infrequent.
7. There is increase in weight and bulk.
8. Menorrhagia is more common.
9. Pregnancy is very rare, but when it occurs patients get worse.

10. Melancholic delusions are more often m et with

We next come to consider the beneficial effects of partial thyroidectomy. Steirlin collected 29 cases in which a portion of the gland was removed, and in 22 of them complete recovery ensued. Wette collected 26 of what he considered undoubted cases in which removal of portion of the gland was followed by considerable improvement and often by a distinct cure, in fact he says that the altered gland is the cause of the disease, and that operation is the only satisfactory treatment.

Putnam, of Boston, has found removal successful in curing the disease, but says, that while there is little risk of death there is great risk of considerable temporary prostration and laryngeal paresis.

Frieberg, of Cincinnati, recommends it in severe cases that will not yield to medical treatment.

Booth and Newton, of New York, have also recorded satisfactory results from operation.

There is not much to be said either for the beneficial effects of medical treatment directed towards reducing the size of the gland, or to the fact that the introduction of thyroid juice into the system in health produces certain effects similar to symptoms of ex. goitre.

Certainly pressure, ice, and the inunctions of red iodide of mercury externally and the administration of belladonna and ergot internally, all of which may be said to aid in reducing the size of the swelling or in diminishing the secretion have been credited with at least as good results as any other therapeutic agents.

The administration of the juice in health has been followed by relaxation of the arterioles, rapid heart action, diuresis, slight rise of temperature, and an overdose in myxœdema has produced flushing, excessive perspiration, muscular spasm, tremor, tumultuous heart action, rapid pulse, and death from cardiac failure.

Now while all these arguments seem more or less to favour what I may call the "glandular theory," and to prove that the goitre is the cause of the other symptoms lest anyone should be led to adopt this view from the plausible nature of the arguments set forth and to consider that we should at once hand over our cases to the surgeon for the purpose of curing them, I will touch briefly on the other side of the question.

In a number of cases of ex. goitre a complete cure has followed the removal of a nasal polypus or the cauterisation of a thickened nasal mucous membrane, while some instances of complete recovery are recorded in which practically no treatment at all has been adopted. Guttman about twelve years ago practised thyroidectomy without any result. Kocher, of Berne, had a case which died the night after operation, and four cases in which no result was notified, and he says the patients have as little chance from operation as if they suffered from malignant goitre. Strümpell, in one case, partially removed the gland and the patient died. While Mannheim as the result not only of great personal observation but also of extensive research in the literature of the subject considers that unless for urgent dyspnœa operation should not be undertaken, and he asserts that only twelve of Wette's cases were genuine Graves' disease, and of these three were unsuccessfully operated on, two were moderately successful, and the others were doubtful. Four of his own forty-one cases were operated on and only one seems to have received partial benefit. He says the most successful treatment is a dietetic and hygienic one which ensures physical and mental rest in the widest sense, and that experience shows electricity to be useful, but the utmost that therapeutics can effect is perceptible improvement, whilst a complete cure is beyond it.

In conclusion, it may be of interest to mention that this disease has been observed in animals. Two cases are reported from St. Petersburg, the first that of a four year old thoroughbred horse, which after a long gallop exhibited abnormally strong and frequent arterial pulsations, cardiac palpitations, and progressive weakness, the thyroid body was found tumefied, and sixteen days after marked double exophthalmos appeared, and after a month's illness the colt died. The second case was that of a small pet bitch, seven years old, in which the cardinal symptoms were present, but were cured with iodine in three months. In the Veterinary Reports for the Kingdom of Saxony, 1890, Roder cites the case of a cow in which palpitations, arterial pulsations, enlarged thyroid and intense double exophthalmos had existed for four years. Finally a somewhat doubtful case has been reported by Professor Cadiot, of Paris, in which a gelding exhibited cardiac palpitations, a bounding pulse, great hypertrophy of the thyroid gland, but no exophthalmos. A reference to these interesting cases will be found in the *Lancet*, of Aug. 20th, 1892.

◆

Selected Prescriptions and Therapeutic Notes.

145.—For Whooping-Cough :—

℞ Sulphonal, gr. j ;
Creasoti, ♏ ij ;
Syr. tolutani ;
Aquæ, āā ʒij.

M. Two teaspoonfuls to be given every two hours.

The Practitioner.

146.—For Bronchitic Asthma :—

℞ Extract : stramonii, gr. ⅛ ;
Potassii iodidi, gr. v ;
Ammonii carbonatis, gr. iv ;
Tincture lobeliæ æthereæ, ♏ v ;
Aq. chloroformi, ad. ℥ss.

M. A tablespoonful every four or six hours.

The Practitioner

147.—Colourless Iodine Ointment :—

℞ Iodi, gr. xx ;
Potassii iodi, gr. iv ;
Sodii sulphitis, gr. xl ;
Aq. qs.

M. Rub the salts with the water until the solution becomes colourless, then add

Adipis benzoati, ʒj.

Atlanta Clinic.

148.—For Neuralgia :—

℞ Liq. arsenicalis, ♏ iij ;
Tinct. gelsemii, ♏ x ;
Liq. strychniæ, ♏ iij ;
Glycerini, ♏ xx ;
Aq. destill, ad ʒj.

M. For one dose. To be repeated three times a day after meals.

149.—To Assuage the Thirst in Diabetes :—

℞ Pilocarp. nitratis, gr. vij ;
Sp. vin. rectificati, ʒj ;
Aq. destill, ʒij.

M. The tongue to be moistened with five or six drops of this mixture four or five times a day.

La Medicine Moderne.

THERE will shortly be a vacancy for a medical superintendent at the Earlswood Asylum for Idiots. The salary is £500, with furnished residence, &c. Full particulars can be obtained of the Secretary, 36 King William Street, London, E.C.

Clinical Records.

HOPITAL HOTEL DIEU, PARIS.

Case of Atrophic Cirrhosis in a Woman, æt. 22. Repeated Hæmatemesis from Varicose Veins of the Œsophagus—Death—Post-mortem.

By M. Cornet, Interne at l'Hôtel Dieu.

The rarity of this disease, and the interest which is created by the study of varix of the œsophagus renders publication of this case desirable. The patient was a servant, æt. 22. Father and mother healthy. Had no eruptive fevers in infancy. No other disease present. Denies alcoholic excess. Two years ago she had a miscarriage at seven months followed by peritonitis. Last year had an eruption on her body, which has left no trace, and of which the nature is unknown. For a long while has had a slight cough and slight blood-tinged expectoration. Within the last three days she vomited scarlet blood on two occasions—about a pint each time; and again on the way to the hospital.

On admission the patient was in a fainting condition; pulse 124. No pain in the stomach. Nothing discoverable in the abdomen or lungs. The liver does not extend beyond the borders of the false ribs. The heart-beats in the 4th spaces; sounds normal. No œdema. She was ordered ice, ether, and ergotine by injection. Sitting position. Two hours later again vomited about 300 grams of dark blood containing no particles of food. She again shortly vomited a quantity of clear ropy fluid with blood suspended in it, but no food. Hæmorrhage was always preceded by cough; and the blood flowed at the same time through mouth and nose. On examination only one painful spot was discoverable in the epigastric region. Ice was applied to the epigastrium, and perchloride of iron in 20 drop doses given internally. The patient was restless during the night, and in the morning was comatose with stertorous breathing; pulse filiform and rapid. The condition suggested uræmia, but there were no signs of that. She died 30 hours after admission to the hospital.

Autopsy.—Lungs sound and free from adhesions. The heart, which seemed small, was without valvular lesions, and contained little blood. The peritoneum was intact; no adhesions between the bands of intestines. No ascites. The liver was remarkable for its colour and texture; it was cirrhotic and extremely atrophied. It was so hard that it emitted a sound under the knife. Weight 240 grams. The spleen was large, cirrhotic and divided by white fibrous bands. The stomach and pylorus were intact. Extending for 5 centimètres at the lower end of the œsophagus was found a remarkable development of varices. These were very prominent, and extended over the whole circumference of the œsophagus. They extended into the stomach some 2 or 3 centimètres. An ulcer the size of a lentil developed on several veins was found at the cardiac extremity. The whole of the large intestine contained blood in clots hardly dark in colour; no ulceration; some vascular congestion. The kidneys congested, but sound.

Remarks.—A young woman having suffered from spitting of blood for about 8 months and from vomiting of blood for two days passes into a comatose state and dies. The autopsy reveals an atrophied liver and varices at the termination of the œsophagus. The difficulties of diagnosis were enormous. All the authors who have written on the subject insist upon the impossibility of diagnosis. The general tenour of the records of such cases runs somewhat as follows: "Atrophic cirrhosis in a man aged between 30 and 40. Hæmatemesis more or less abundant. No ascites." The present case was rendered the more difficult of recognition by the age of the patient, and the nature of the case remained an enigma until revealed by post-mortem examination. The classical diagnostic error in these rare cases is to mistake them for cancer or for ulcer of the stomach. In the present case cirrhosis was not suspected. It seemed negatived by absence of digestive troubles and of ascites, and it seemed impossible to suspect such a condition of liver in a patient, æt. 22.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held May 10th.

The President, Professor Thomas Savage, in the Chair.

Mr. F. Bowreman Jessett showed a large

FIBROMATOUS UTERUS, PART OF WHICH HAD UNDERGONE SARCOMATOUS DEGENERATION.

He had begun the operation per vaginam, but being unable to draw the tumour down, he opened the abdomen and so removed it without difficulty. During the operation he considered the alternatives of removing the uterus in several pieces or of emptying it, but decided that this procedure would involve too much risk of infecting the peritoneum. The patient had done well.

Dr. Purcell, who had assisted Mr. Jessett at the operation, commented on the difficulties which the case presented. The ovary and tube of one side were adherent to a coil of intestine; and any attempt to forcibly separate these adhesions would probably have had very grave consequences.

Dr. Bantock thought that the interest of the case lay rather in the pathological condition of the tumour than in the *modus operandi.* Out of nearly 200 cases of uterine fibroids on which he had operated he had seen only one in which there was malignant disease, and that was a sarcoma of the lower segment of the uterus. He removed the whole, but the patient died not very long afterwards from the progress of a similar and co-existing vaginal growth. The method employed by Mr. Jessett was the same in principle as Freund's method for cancer; the difference lay in the manner of dealing with the peritoneum.

Adjourned discussion on Dr. Routh's paper on

THE CONSERVATIVE TREATMENT OF THE UTERINE APPENDAGES. (a)

The discussion was opened by

Dr. Heywood Smith. He said that some men, the non-operators, often see a large proportion of the failures of the operators; because a patient in whose case an operation has not succeeded will often not return; conversely, non-operators are apt not to see many of the successes of operations. He considered that the opinions respecting spermin and other substances secreted by the ovaries must be received with caution; there was very little evidence that this secretion occurred, and *à priori* it was unlikely, inasmuch as the ovary was a "closed" gland. If Dr. Routh's views as to the awful consequences of removing appendages were proved, the results should absolutely deter them from operating; but it was evident from what they all knew of these results that these conclusions could not be accepted. Moreover, in dealing with any case that came before them they were obliged to consider the suffering, the disablement, of the patient, and her social position in relation thereto. If a patient was in a position to lay up for weeks or months an expectant line of treatment might be warranted; but in the case of poor women who had to earn their living this was impossible, the alternative for them was starvation or the workhouse. After criticising the fallacy of deductions from post-mortem records, Dr, Heywood Smith discussed the "conservative operations." As Dr. Routh had insisted so much on the "unsexing of the woman," it was well to point out that many of the conservative operations were necessarily followed by sterility. It was easy to talk of resections of the tubes, ignipuncture of the ovaries, &c., but these operations were no safer than removal, and if the function of an organ was lost what advantage could accrue from leaving it or a part of it when diseased? Curetting was sometimes good as a prophylactic measure, but in other cases it might start fresh mischief. The aspirator also might be safe when an abscess which had fixed the ovary was bulging palpably into the vagina; but in the case of a pyosalpinx, for instance, the peritoneal cavity might be infected with a fatal result. He protested against the use of such terms as "castration," "eunuchs,"

(a) This paper has already appeared in the Medical Press and Circular.

&c., in relation to this subject; they were misleading and harmful.

Dr. **Purcell** heartily endorsed Dr. Routh's paper, which he thought was an admirable one, and would act as a "salutary brake" on the too general operative measures.

Dr. R. T. **Smith**, while admiring the labour bestowed on the paper, objected to being told that when he removed diseased appendages he was "castrating" women. He had done the operation often, but never with the idea which the word implied. At the same time he quite shared in Dr. Routh's anxiety that no operation should be performed unnecessarily. The whole matter of spermin was new to him, and he had hoped Dr. Routh would have taken the other side, and objected to these injections. He agreed that in cases of salpingitis associated with menorrhagia, the attention should be first turned to the uterus: he had adopted this method with the best results.

Dr. **Macnaughton Jones** thought Dr. Routh deserved to be complimented and thanked for the great trouble he had taken in compiling the statistics and literature of the subject; he also admired his tone of moderation. He strongly objected to the term castration, which implied mutilation and the removal of healthy organs. Ovariotomy, on the other hand, was for the removal of diseased parts. When once there was disease, the patient should not be left to take her chance of a cure; and if a man refused to operate, simply from prejudice and fear, that man was little short of criminal if, as might happen, the patient suddenly died, from rupture of the blood cyst or suppurating tube. Dr. Macnaughton Jones then quoted several extracts from the writings of Dr. Mary Dixon Jones, who wrote as a woman as well as a doctor. While she made "the uncompromising sweep of excluding all cases from the operation except where there is hopeless disease of the organs themselves," she maintained that once diseased, and their function irretrievably lost, "the removal of the diseased appendages was only to save her from more serious possibilities. With or without an operation she was sterile." He could not admit that there was true clinical and physiological analogy between the changes produced by the "climacteric" and those resulting from ovariotomy; nor was it his experience that after this operation it was a frequent thing to see women becoming inordinately fat; infantile in their intellect, or masculine in their appearance and sympathies. He distrusted statistics altogether, and thought that deductions from post-mortem records were specially unreliable. It would be a great mistake if, as gynæcologists, they were to be unduly influenced by mere sentiment, and were to refuse to attach proper weight to the surgical principles by which all other surgeons must be guided.

Dr. **Bantock** felt that there was very little in the paper with which he could agree, because his own experience pointed to different conclusions. The results of Mrs. Brown's experiments, with extracts from the ovaries of animals, were of but little value, from the very nature of the cases on which she experimented; they were women affected by "debility caused by age, insomnia, hysteria, uterine affections, &c.; it was probable that hysteria was the leading feature in all of them. Dr. Keith was quoted as stating that insanity followed hysterectomy in 10 per cent. of the cases; he had himself done nearly 200 hysterectomies, and had not even a single case followed by insanity, when there was no predisposition to it. As to Dr. Baldy's case of melancholia after rectocele, that had obviously but an accidental association with operations on the sexual organs. Like other speakers he placed little reliance on the records of autopsies; if operations were performed only for such diseases as directly threatened life, they would do only one-tenth of the present number. Nine-tenths were operations of expediency: would a man die of piles if not operated upon? Moreover, it was ridiculous to talk of the mortality of a disease as being the only thing to consider; it was suffering mainly which they had to relieve, especially in cases where women were unable to earn their living, and whose lives were a burden to them. Many of the so-called conservative operations were really "meddlesome surgery," for they did not restore functions that had been lost, and often left behind parts that were diseased.

Mr. **Jessett** felt that Dr. Routh's views must be received with considerable respect; but it did not seem to him that the whole of the paper was germane to the subject. He would consider only the first and the last two "conclusions." If it were proved that the ovary secreted "spermin," and that its loss was an injury to the body, then, of course, they could never advise the removal of the appendages, especially if Dr. McFarlane's conclusion were correct, "that it may be affirmed, that more women, 10 to 1, have been consigned to hospitals for the insane (victims of needless or unskilful surgical operations) than have been restored to reason by the most commendable and skilful abdominal surgery." But Gorzet found that the ovarian extract had no effect at all, and Mrs. Brown's experiments were hardly extensive enough to be conclusive. With the fifth conclusion, "that complete castration had been practised too frequently and often unnecessarily; but it then took the form of an epidemic, as other things have done before and since; not long ago it was the fashion to diagnose all right iliac pain as typhlitic, and to advise removal of the vermiform appendix. Mr. Jessett related an illustrative case in which he had removed the ovaries; and concluded by thanking Dr. Routh for his paper.

Dr. **Routh**, in reply, regretted that some of the speakers had spoken with a little unnecessary heat; he would, however, excuse them as no doubt they felt strongly. He pointed out that several of the speakers had misapprehended the drift of his statements on the subject of spermin, perhaps they had not read the paper with sufficient care. So far from recommending the practise of injecting these fluids, he expressly deprecated it, as they would find by referring to the paper. The whole question of ovarian secretion was a physiological one, and could not be decided on any *à priori* grounds. Much objection had been made to the word "castration;" it was the term used in France, Germany, and America, and by no means implied that the ovaries were healthy. Further he disclaimed the responsibility of sharing the opinions he had quoted in his paper, to review the whole subject in an impartial spirit it was necessary to quote views with which he did not agree, as well as those on the other side. He defended the use of the aspirator on the lines he had laid down, with antiseptic precautions, and quoted recent results in support of the practice.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, May 4th.

Sir W. Stokes in the Chair.

NASO-PHARYNGEAL FIBROMA.

Mr. **Woods** read a paper on Naso-pharyngeal Fibroma. The patient whose case was detailed was a young man, æt. 24, who, about May, 1888, noticed a difficulty in breathing through his nostrils. This difficulty progressed to complete nasal obstruction, associated with giddiness, failure of memory, and great drowsiness. Towards the end of 1889 he was operated on by two American surgeons consecutively but without being materially bettered. In 1891 he put himself under the care of Mr. Thornley Stoker who operated on his nose from the front, but who did not attempt a radical removal of the growth owing to the extent of its attachments and the fierceness of the hæmorrhage. Mr. Stoker, in January, 1892, transferred the case to Mr. Woods. At this time the whole naso-pharynx and the greater part of the left nasal fossa were filled with a typical fibroma. Nasal respiration was completely stopped, and his voice was without nasal tone. Mr. Woods repeatedly operated with the galvanic snare and lopped off pieces until the snare would no longer grip. He then devised an instrument which he calls a "galvanic curette," and which consisted of a semicircle of platinum wire brazed to the ends of two insulated copper rods; the platinum arc could be heated at will by an electric current. With this instrument he ploughed the tumour away piecemeal sometimes attacking it from the front through the nostril and sometimes from behind through the naso-pharynx. The patient never suffered very much, and the bleeding was never very considerable. By January, 1893, the tumour was completely removed and the patient perfectly well again. His voice was quite normal and admitted of his adopting the stage as his profession. The advantages claimed for this method of operating are the following :—1. It is less dangerous and more certain than any other method, experience proving the bleeding to be trivial. 2. The patient is neither maimed nor disfigured, as frequently happens in cases of operation where the nose is cut or the palate divided by any of the well-known methods. 3. There is no danger of injuring healthy structures, since the operator can see exactly what he does.

Sir William Stokes congratulated Mr. Woods on his success, and said that formerly this case would have required to be treated by an operation which would have necessitated great cicatricial deformity, in which there would have been danger from hæmorrhage at the time of operation, and which would have been difficult of performance. Mr. Woods' method gets rid of all these objections, and the shock to the patient is infinitely less. It seems to him that nasal polypi were less likely to recur after removal by the galvano-cautery than after removal by other methods. Perhaps this might be due to the firm cicatrix produced by a cautery.

Mr. Swan wished to know could this method be applied to removing osseous growths.

Mr. F. Nixon asked Mr. Woods did he think the disappearance of the somnolence to be due to the removal of the tumour.

Mr. Maxwell said that inability of concentrating one's mind upon work is a rather common symptom in adenoid tumours occurring in the naso-pharynx. Their removal often resulted in the patient being freed from this symptom. He had occasionally noticed that patients, shortly after operation, complained of pain in the occipital region.

Dr. Myles mentioned a case in which he had assisted the late Dr. Robert M'Donnell. The patient had a recurrent growth in the naso-pharynx. It had been previously operated on by the snare, but had recurred. Dr. M'Donnell determined to try and gouge away the growth from the front. He succeeded in detaching the tumour, but the hæmorrhage was something appalling. The patient recovered, but the growth afterwards recurred and came under the care of Mr. Thomson at the Richmond Hospital.

Mr. Thomson said that he had not much difficulty in removing the recurrent growth when the case came under his care. The tumour was reached by splitting the nostril and raising the lip. Recurrence took place in fifteen months, and the tumour was again removed. The boy lived for two years, but he had not been able to find out what was the cause of his death. The only objection he saw to Mr. Woods' method was that it was rather a prolonged procedure. He did not think any cicatrix would prevent the recurrence of a tumour if the tumour was one of those which had a tendency to recur. By this method the disease might be more thoroughly attacked and got rid of, and this element seemed to have more to do with preventing recurrence than a firm cicatrix.

Mr. Chance wished to know would the time of treatment be shortened if a plastic operation giving greater room were first done and then Mr. Woods' instrument immediately applied.

Mr. Woods, in reply, stated that diminished likelihood of recurrence of the tumour he considered to be due to the method being more thorough. He saw no reason why the instrument should not be used to remove exostoses, particularly those in the external auditory meatus. In all cases of naso-pharyngeal tumours there existed in the patient great stupidity. The drowsiness and somnolence he considered to be this stupidity in a greater degree. With regard to Mr. Chance's suggestion, he did not think that it could be followed, because the very essential for success in the operation was that you should see exactly what you were doing. The bleeding consequent on a plastic operation would prevent this.

Mr. Wheeler read a paper entitled "On Hydroceles of the Neck."

Sir Wm. Stokes said that, as far as his experience went, the treatment of tapping the hydroceles and injecting iodine was not successful. Either the cyst quickly refilled or such extensive inflammation was set up as to endanger the patient's life. He advocated free incision and dissecting out the cyst. In a case he had operated on last January he had found the wall of the cyst exceedingly thin and the contents of the consistence of glycerine. The submaxillary gland he also found enlarged, and he removed it. Since the operation the patient has had no recurrence of the disease. He had been a soldier in India, and when there, four years ago, became troubled with this swelling. It was tapped, but recurred, and was tapped twice again. After the last tapping the disease did not recur for three years, when the patient came under his care.

Mr. Swan said he thought these hydroceles were due to a failure of closure of the branchial clefts occurring in the embryo. Many years ago he saw a case of a lady with a supernumerary auricle in the neck. She developed what he believed to be a hydrocele of the corresponding branchial cleft, for a cystic tumour arose extending from the auricle deep into the substance of the neck, and ultimately reaching the wall of the pharynx. It burst in front of the auricle.

Mr. Wheeler, in reply, stated that in all cases of recorded hydrocele the fluid withdrawn had been quite watery and not unlike glycerine in consistence. He doubted, for this reason, whether Sir Wm. Stokes' case was a true hydrocele. A true hydrocele was usually too deeply attached to admit of dissecting it out.

The Section then adjourned.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, May 16th, 1894.

The President, Dr. T. S. Clouston, in the Chair.

DISCUSSION ON MASSAGE.

Dr. Halliday Croom, who introduced the subject, first gave a short historical sketch, and then proceeded to describe the different forms at present in vogue, premising that it was a good thing that good men now devoted themselves to its practice. He divided massage into four classes :—(1) simple massage, with its different movements of tapping, kneading, and hacking ; (2) the Weir Mitchell treatment ; (3) the Swedish system, and (4) mechanical massage, where the patient is rubbed, shaken, and pummelled solely by machinery. The first, or simple massage, he had found in his experience to be good in constipation or neurasthenia, but not advisable in cases of gall-stones, in many of whom he had seen peritonitis set up. The Weir-Mitchell treatment had, in his own hands, led to a few successes, but many failures, and, for his part, he was disappointed with it. He had, however, seen some marvellous results at the hands of others. In his own department of gynæcology, massage was used for all sorts of diseases, both externally and internally. Of these, the internal was most repugnant to all but Frenchmen and some Americans, while the external form proved to be dangerous now and then. He had seen a hæmatoma formed by it, and grave results could follow its application for pyosalpinx, for which it has been recommended. For gynæcological massage, the operator must have "clean hands and a pure heart."

Dr. Keiller, who followed, described the methods and detailed some cases.

Dr. J. H. A. Laing laid great stress on the advantage of combining massage with exercise short of over-fatigue. In constipation, for instance, the action of massage was much increased if the abdominal muscles were exercised at the same time by bending movements. These movements, however, should not be carried on to over-fatigue. The same thing applied to dyspepsia. In the treatment of neurasthenia by the Weir-Mitchell system, his rules were very much too slavishly carried out. All patients did not require exactly the same treatment, and especially the prohibition of reading was, in his opinion, often a mistake. For gynæcological cases, the external method was the only form admissible, while the addition of body movements to the massage was of use notably in dysmenorrhœa. In Sweden and Germany no oil was used, but he thought that it was of use occasionally. Another very common mistake arose from the idea that an hour was the proper period for a *séance*, while in many cases, at first at any rate, a quarter of an hour was quite sufficient. The time depended on the case. He had found muscular rheumatism greatly benefited by it, short of fatigue. He had been struck by the fact that in Paris a patient with a sprained ankle was able to go about on it without pain, in fact, was cured in seven days, while in this country three weeks was the usual time allowed. This was due to the use of massage which should be begun on the day after the accident, beginning just above the sprained joint.

Dr. **Allan Jamieson** had found massage of service during the early stage of baldness and, combined it with the application of warm water, in symmetrical diffuse scleroderma.

Dr. **Joseph Bell** said that there were sprains and sprains, some of which when severe were not benefited by massage. He advocated the treatment of Colles' fracture without splints and with the use of massage. In those cases of synovitis of the knee-joint in weak young people due to weakness of the muscles of the thigh and simulating white swelling, massage was of great service. In neurasthenia, in his opinion, the most necessary thing was a good nurse.

Professor **Chiene** divided massage into (1) gentle, for the relief of pain, (2) firmer, for the prevention of adhesions, and (3) firmer still, to break down old adhesions. In bad fractures massage should be begun after the first week, splints being put on in the intervals. He thought with regard to the question of early tuberculosis that the white swelling of joints oftener occurred after mild than severe injuries, and that these cases would be fewer if rubbing was practised early.

Dr. P. A. **Young** gave details of some cases, and supported the use of body exercises along with massage in constipation.

Dr. **Cathcart** had noticed that massage of a limb had by amputation set up fibrillary tremors in the muscles, and he thought that similar rubbing over a gland might stimulate its action by fibrillary movements. He would hesitate before recommending its application to tubercular joints even at an early stage.

Dr. **Somerville**, of Glasgow, who had lately been in Sweden, spoke well of the combination of massage and medical gymnastics. In Sweden he had even seen the heart massaged, tapped, &c., combined with gymnastics in a case of mitral incompetence.

Dr. **Carmichael** deprecated the growing practice of leaving the cases suitable for massage under the sole charge of a masseur without personal supervision of part at least of the treatment.

Dr. **Affleck** had found it useful in alcoholic neuritis, chronic rheumatism, and in insomnia, but had had many failures in cases of neurasthenia.

Dr. **James Ritchie** recommended the dry form, although on occasion he had found the use of oil of service.

Dr. **Hunter** wished to warn members against the indiscriminate use of massage in supposed neurasthenia, instancing a case in which the underlying cause was spinal disease, and in which it proved hurtful rather than beneficial, while

Dr. **Playfair** also warned the members that the treatment must be thorough, and that much depended on the nurse.

Dr. **Stiles** thought massage of use in very early cases of tubercular disease.

Dr. **Clouston** said that when this system of treatment was first advised he obtained a striking success in a case of melancholia, and thought that the millennium had arrived with regard to such mental diseases, but later cases failed to substantiate the first results. It had proved of most benefit in cases of melancholia, especially if it were combined with exercise, but some of them were rendered much worse, especially by the seclusion. In patients suffering as a result of trophic deficiency much good might be done. He finished by proposing a resolution, which was carried by the Society unanimously, that the members of the Society protested strongly *against the use of internal massage of the female pelvic organs.*

The annual election of candidates for Pensionerships and Foundation Scholarships of the Royal Medical Benevolent College, Epsom, was held on Thursday last. The names of the twenty-two successful competitors will be found on reference to our advertisement columns.

GENERAL MEDICAL COUNCIL
OF
EDUCATION AND REGISTRATION.

SPRING SESSION, 1894.

The President, Sir Richard Quain, Bt., in the chair.

SIXTH DAY.—Monday, May 28th.

The Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin.

Sir Dyce Duckworth resumed the discussion on the resolution which he moved on Saturday. He urged that the examination of this conjoint board was admitted to be neither creditable nor desirable. This was particularly the case in respect of the Apothecaries' Hall of Dublin, of which body the examinations had invariably been the subject of unsatisfactory reports. He held that this body was incorrigible, and he said that in his opinion the time had come for the College of Surgeons to break with what he called the "left-handed board" in Ireland. He insisted on the fact that in arriving at this report the Examination Committee had been animated by a strong feeling in the interests of the profession.

Mr. **Bryant** seconded the resolution, and urged upon the Council that there was no valid reason for postponing action in the matter.

On the suggestion of Sir William Turner the resolution was taken in two parts, the first part of the resolution simply declaring the opinion of the Council that the examinations in question were "insufficient."

Dr. **Atthill** said that as the representative of the College of Physicians nothing but feelings of duty had induced him to take the position he was compelled to take. He discussed the details of the reply of the management of the conjoint board to the memorial of the College of Physicians, and pointed out what he stated to be inaccuracies. He complained of the unfair competition which the conjoint board of the Royal Colleges had to contend with in the face of the laxity of the incriminated board, and he concluded by saying that the matter before the Council was very simple, being, in fact, simply the question whether yes or no they intended to allow one examining board in the United Kingdom to become the refuge for the dullards who could never learn, and for those who preferred to spend their days in idleness.

Sir **Philip Smyly** said the conditions laid down by the Council had been placed before the Conjoint Board and were being fully complied with. He was instructed, on behalf of the body he represented, to acknowledge the irregularities complained of, but he was in a position to assure the Council that changes had been made which would secure them against any repetition thereof.

Dr. C. **Moore**, on behalf of the Apothecaries' Hall of Dublin, endorsed the remarks that had fallen from the preceding speaker, and he pledged himself and his Board to do all that could possibly be done to meet the wishes of the Council.

Thereupon the resolution, as divided, was agreed to.

Sir **Dyce Duckworth** then moved the second part of the original resolution to the effect that a representation be made to the Privy Council.

Dr. **Heron Watson** called attention to the fact that his amendment had not been disposed of, and by direction of the President it was taken as an amendment to this motion.

Dr. **MacAlister** pointed out that as the Council had formally recognised the examination to be insufficient they had no option but to represent the matter to the Privy Council.

Dr. **Heron Watson** then moved his amendment to the effect that, as the Board had promised to remedy existing defects, the Council should not forthwith make any representation to the Privy Council, but should direct that all the examinations of this Conjoint Examining Board, whether final or previous, should be specially visited, inspected, and reported upon, during the ensuing twelve months.

Dr. **Pettigrew** seconded the amendment which was agreed to by a majority of 8, out of 20, and was subsequently adopted as a substantive motion.

Preliminary Examinations.

The next item of business was a report by the Education Committee on Indian, Colonial, and Foreign preliminary examinations. It was stated that certain of these examinations were not up to the Council's standard but before definitely removing them from the list of preliminary examinations recognised by the Council it was suggested that copies of the report should be forwarded to the bodies interested inviting them to comply with the Council's recommendations on this subject.

On the motion of Dr. **Tuke** it was decided to obtain at least two copies of the *Calendars* of all Bodies conducting examinations recognised by the Council.

Penal Procedure.

Mr. **Carter** moved a resolution, drafted by Mr. **Muir Mackenzie**, providing that in penal cases, when a person had been adjudged guilty of the offence charged against him, the Council should either proceed to decide forthwith whether or not the offence amounted to infamous conduct in a professional respect, or might postpone a decision upon these questions and adjourn the inquiry *sine die* or until the next or some future session.

This modification of the Standing Orders is tantamount to authorising the Council to bind the defendant to come up for judgment if called upon.

The motion was seconded by Sir **Walter Foster** and was agreed to.

Various items of formal business were then disposed of.

Dental Representatives.

The Council then took into consideration the proposal emanating from the British Dental Association urging the addition to the Council of a member or members cognisant of the requirements of dentists.

Sir **Wm. Turner** moved that the Council had no power to take cognisance of such a proposal.

Sir **Walter Foster** was of opinion that the dentists were hardly treated in having no representative on the Council, but he agreed that the Council had no power to give effect to such a resolution.

Sir **John Simon** said he did not see why dentists should be represented on the Council more than any other special group of practitioners.

After some discussion the Council adopted Sir Wm. Turner's negative resolution, and the matter then dropped.

Advertising Dentists.

Mr. B. **Carter** moved, "That the attention of the Council having been called to the practice of advertising by certain dentists, it is hereby resolved that the issue of advertisements of an objectionable character, and especially of such as contain either claims of superiority over other practitioners or depreciation of them, may easily be carried so far as to constitute infamous conduct or disgraceful conduct in a professional respect."

After being seconded by Sir **Dyce Duckworth**, the motion was agreed to, and it was also ordered that certain pictorial and other advertisements exhibited on the walls of the Council should be referred to the Dental Committee for their consideration.

This concluded the business of the Session.

◆

Germany.

[From our own Correspondent.]

Berlin, June 2nd.

At the meeting of the Medical Society of the 30th ult. Hr. Leyden related an interesting case of

Phosphorus Poisoning.

The patient was, on Feb. 1st last, shot in the temple by her young man, and a second time in the region of the heart, and about the same time he gave her a dose of phosphorus. The patient was at once removed to the Charité, when the stomach was thoroughly washed out with at least 45 litres of water. The washed-out fluid not only smelt of phosphorus, but it was distinctly luminous. Three doses of cup. sulph. had no effect, but after ipecac. and antimony were given vomiting of about 400 grm. of brown-greenish fluid took place. The patient was then given ol. terebinth. The wound in the temple had healed without cerebral symptoms. The bullet that had penetrated the chest gave rise to no special symptoms. The day after the attempted poisoning slight albuminuria and swelling of the liver were noted, and continued for some time. The excretion of nitrogen was also increased for a time. These changes pointed to moderate phosphorus poisoning. Phosphorus acted mostly after it had passed the stomach, and if this was washed out sufficiently early and thoroughly, one might hope to prevent a fatal result. The second bullet had not yet been found. On the fifth day pericarditis developed, with friction sound and increased cardiac dulness, pulse 140, slight fever. The speaker was of opinion that the heart had been injured by being grazed by the bullet. At the posterior part of the thorax there was a patch of dulness which was pronounced to be extravasated blood. Puncture confirmed this pronouncement.

Jubilee of the Society for Obstetrics and Gynæcology.

The jubilee of this Society, the oldest of the kind on the Continent, was celebrated on the 9th and 10th ult. in the way such functions are usually carried out here. The Society was founded by Carl Mayer, who in the year 1844 was the means of uniting 10 practitioners of the city into a society (called the Geburtshelfleshe Gesellschaft), the meetings of which were at first held in his own house.

One of the earliest subjects brought before the Society was that of the artificial feeding of infants, and it still remains one about which a deal more will have to be said. Not only practical subjects were discussed, but also those relating to pure science. One of the four addresses before the Society was on the discovery of Bischoff, just then made public, on the periodical ripening and extrusion of the ova. On account of this tendency towards science the three distinguished Berlin pathologists, Virchow, Reinhardt, and Leubuscher, were induced to join in the labours of the Society as members extraordinary, and it was through this combination that gynæcology was first put upon an anatomical basis. This new impulse led to good results, as the publications of the Society show. These for the first 25 years were entitled "Proceedings of the Obstetrical Society (Verhandlungen der Gebustshelflichon Gesellschaft)," and the next six years, "Contributions to Obstetrics and Gynæcology (Beiträge zur Geburtshilfe, Gynækologie)." Carl Mayer, whose son-in-law Virchow became, died in 1868. After his death Ed. Martin became President, and after him the late Carl Schroeder. During the latter part of Schroeder's presidency Prof. Gusserow was associated with him in the management, and after the death of Schroeder in 1887, Prof. Olshausen, the latter's successor in the University Chair of Obstetrics, became joint manager. The Society took on its present name in 1876, when it coalesced with the Gynæcological Society, which originated in 1873.

The celebration took the form of an extraordinary Gynæcological Congress, to which distinguished *confrères* made their pilgrimage from even distant lands. Amongst those present were the following, whose names are household words amongst gynæcologists:—Freund, Strassburg; Winckel, Munich; Chrobak, Vienna; Fritsche, Bonn; Schultz, Jena, Slawiansky, St. Petersburg; Pozzi, Paris; Pasquale, Rome; Vuillet, Geneva, &c. Nearly all the hospitals and societies sent deputations. The large hall of the Langenbech Haus, in which the Session was held, was ornamented with the laurel-crowned statue of the founder and the crowned marble busts of his successors, Ed. Martin and C. Schroeder. Prof. Gusserow greeted the assembly; the Festschrift published in celebration of the event was then distributed, after which a number of honorary members were elected. Prof. A. Martin then delivered the "Fest" report. The "Fest" address was to have been delivered by Prof. Olshausen, who was unfortunately prevented by illness from taking part in any of the proceedings. The address was, therefore, read by Prof. Peit. Then followed so many congratulatory addresses from so many public and scientific bodies that the wonder is how all the business was got through successfully in the time at their disposal. Not the least interesting event of the day was the address delivered in French of Prof. Pozzi, representative of the Surgical Society of Paris. In his reply to the address Prof. Gusserow expressed his pleasure that the learned of one and the other side of the Rhine could work together on the neutral ground of science. A dinner at the "Rerchshof," and an excursion to the Havilsee, near Potsdam, concluded the celebration.

SUNK CONTINUOUS SUTURES IN HERNIOTOMY, &C.

Hr. Schede discusses this important subject in a late Report of the Hamburgh Eppendoifer Hospital, on the occasion of an operation on an enormous umbilical hernia in a child, æt. 1½. Schede made use of a form of suture that had already given him good results in similar cases. He now uses only silver wire which has been boiled in a one per cent. soda solution, and then placed in a three per cent. carbolic solution. First of all three to four sutures are passed through the whole thickness of the abdominal wall, but not tied at first. By putting these sutures on the stretch the edges of the wound are brought close together, an assistant seizes the sheath of the rectus on each side with a pair of strong forceps, and a large number of silver wire sutures are inserted, which only pass through the sheath of the rectus and the peritoneum. The upper edges of the wound are then brought together by tying the sutures first inserted. These latter are removed in about ten days.

These sunk wire sutures have now been used by Schede in 121 laparotomies of the most varied kind, and in only 4 of them have slight hernial protrusions taken place. In 163 cases of herniotomy a permanent cure was determined in 90 per cent. of the cases.

POLICE WARNING IN REGARD TO ICE.

On the 27th ult. the Kgl. Polizei President announced to the public that investigations made in the Imperial Health Office had shown that the ice used in Berlin even when to all appearance of good quality contained disease germs that were capable of development and originating disease. It had become, therefore, probable that the illness frequently observed after partaking of iced drinks did not arise from the coldness of the beverage but from the disease germs taken into the system from the ice. The same thing held good as regarded solid articles of food that had been kept cool on ice, such as butter, &c. The public are, therefore, warned against the use of drinks and foods that have been cooled with ice in the before-mentioned way and rendered possibly dangerous in consequence.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 1st.

GONOCOCCI.

AT the surgical meeting this week, Dr. Finger reviewed the past and present knowledge of gonococci. He said Wertheim was the first to discover these bodies in human serum by means of plate cultivations, but this method was complicated and unreliable. He found uric agar more accurate and easy of application. Concerning the biology of gonococci, he assured the meeting that the microbe flourished better in acid nutrients than in weak alkalines; that they were not fully developed by the ordinary temperature of the room, but commenced to flourish about 25° C., which reached the maximum at 38° C. After this point was past the growth was retarded and was entirely destroyed with 40° C. of temperature; it is equally destroyed by drying. From a forensic point of view he pointed out the practicability of this exact knowledge in foul clothes if kept moist; but if the discharge be allowed to dry the test is destroyed. He has found gonorrhœal discharges capable of being cultivated after lying 36 hours in the ordinary temperature of the room. The microbe is not so sensitive to chemical reagents as some others, silver nitrate one in a thousand, sublimate one in six thousand affecting them slightly after two minutes, but not destroying them. His experiments against immunity showed that they would attack the canal after a perfectly healed condition of acute urethritis as well as chronic. In all the inoculations he is convinced that the gonococcus is the sole irritant. Whatever may be the cause of urethritis posterior he found it always occurring from fourteen to twenty days after inoculation. In many of the inoculated cases inflammatory condition of the joints followed with circumscribed peritonitis in which gonococci could be found 24 hours after inflammation had commenced. In eight patients where exitus letalis was expected, inoculation was three times positive and five times negative. In the former there was little or no fever, while the latter had high temperature. It is an old clinical experience that high temperature during the course of urethritis has the effect of drying up the secretion, which may again recur; a febrile temperature, therefore, acts as temporary immunity against the gonococci; in mammalia this fact is also found also to exist.

With respect to the gonococci found in tissues, he could not understand why Neisser was opposed to this view, when the gonococci could be found shortly after penetrating the fibrous tissue, which had been repeatedly proved and confirmed by anatomical specimens.

Frisch had discovered these organisms in the glands as well as the fibrous tissues in a case of rectal gonorrhœa; he even assures us they were found in abundance in the muscles. The changes produced by the microbe differ according to the cellular structure; in the squamous epithelium the gonococci remain near the surface, while in cylindrical epithelium they are found burrowing deeply in the structure. It would appear that the squamous epithelium acts as a protecting cover, while the cylindrical is a dangerous absorbent. Other dangerous sources are the pouches of Morgagni and the glands of Littre. Before Wertheim it was believed the complications arose from mixed production, but recent investigations connect the gonococci with arthritis the most common, and occurring as a primary cause of gonorrhœa. In an infant eight days old who had double-sided ophthalmo-blenorrhœa agonitis with other affections ensued, and on examining the matter from a puncture a large number of gonococci were found. Where streptococci were present the gonococci exceeded them.

Finger finds the easiest form of colouring the gonococci is with borax-methylbleu, which is five of borax to five of methylbleu to 100 of water; the slide is then washed in a half per cent. of acetic acid, and next treated with alcohol, bergamot oil, and Canada balsam. This method has the disadvantage of making temporary slides, as the preparation will not last longer than three or four months.

Russia.

[From our own Correspondent.]

St. Petersburgh, May 31st.

Bulbar Paralysis after Influenza.

L. **Stembo** has recently been demonstrating some of the influenza sequelæ, believing in Althaus's dictum that "there are few disorders or diseases of the nerve system which are not liable to occur as consequences of grip." He showed a cook, æt. 29, to the Medical Society, suffering from progressive bulbar paralysis. The patient was descended from a good family, no nervous affections having previously been known. At 16 she commenced to menstruate, which appears to have recurred regularly; at 20 she married; husband healthy, and three children were born, the last six years ago. Two years ago was left a widow.

Two months ago she was smitten with a severe attack of influenza, but made a speedy recovery. A month later she observed her speech was impeded, while saliva and discharge came from nose and mouth, with difficulty of swallowing. The speech still became more hoarse and nasal, with pain in the head, till she reached the condition shown at the meeting. She appeared well nourished, skin in mucous membrane pale, bones and muscles well-developed, head of normal configuration, intelligent though much depressed. The brow fell in folds, eyes could be opened and closed, and ocular movement normal. Pupils medium size, reaction prompt, accommodation good, and fundus of the eye normal. The lips are small and thin—whistling and blowing with the lips impossible. The tongue when protruded was tremulous, and appeared thinner than normal, although its movements were complete. The uvula was drawn to the left, and when making efforts to swallow fluids, they would return by the nose. Paresis of the constrictor pharyngis cause difficult deglutition. There was also paralysis of the crico-arytænoideus posticus muscle, leaving a vocal cord loose in the middle. Countenance, taste, smell, and hearing normal; heart, lung, and abdominal organs healthy, appetite good, bowels regular, urine normal in quantity and containing nothing abnormal, sensibility of the skin and accessible mucous membrane of the throat and other orifices of the body, as well as tendon reflex, normal. He concluded that this was a typical case of progressive paralysis, or what might be better termed atrophy of the tongue, lips, soft palate, and larynx (paralyse progressive glosso-labio-pharyngo-laryngée) due to affection of the centre in the bulbus medullæ spinalis, and has been termed by Wachsmuth, progressive bulbar paralysis..

◆

The Operating Theatres.

ROYAL FREE HOSPITAL.

Ovariotomy (Twisted Pedicle).—Mr. **Battle** operated at this hospital for an unusual example of ovarian tumour with symptoms which differed somewhat from those usually met with: the woman, æt. 46, had been admitted from the out-patient department six days before, having applied on account of difficulty in micturition; she presented a swelling of the abdomen which resembled a distended bladder or the uterus at the end of the sixth month of pregnancy; she stated that this swelling had been first noticed five or six months before, but had caused no inconvenience until the last fortnight, when she had experienced difficulty and pain on micturition; a week before she was seized with pain in the abdomen and vomiting, and was obliged to keep her bed for a day or two; since then she had been able to get up, and although the pain had continued there had been no more vomiting. She had had several children, menstruation had been regular, and no enlargement of the breasts had taken place. During the short time since her admission a sound had been passed the normal distance into the uterus, the patient had again menstruated, and examination showed no evidence of pregnancy. The tumour had become more rounded, but remained tender in its upper part, and evidently contained fluid. The temperature was normal, although the tenderness of the tumour continued, and she complained of pain. Before beginning the operation Mr. Battle said he expected to find a multilocular ovarian cyst with partial twist of the pedicle and adhesions to the surrounding parts. He thought that some of the adhesions might be firm and cause trouble, as she gave a history of two somewhat similar attacks two or three months before. The usual median incision was made and a cyst exposed, the walls of which had a purplish mottled appearance. A trocar was put in and the contents of a large cyst evacuated; the opening was then drawn outside the abdomen and the cyst wall, which was adherent throughout, gradually separated from omentum, intestine, and abdomen by means of the finger. The adhesions, which were recent, separated easily, but as they were very vascular, much oozing of blood ensued. The pedicle was on the left side, and had been twisted a half turn, so that it lay in the median line on the front of the cyst; a double ligature was applied to it, and the cyst removed. The space the cyst had occupied was carefully cleansed with sponges, but as the oozing still continued it was thought desirable to insert a Keith's drainage tube into Douglas's pouch. The wound was closed in the usual way, and perchloride dressings applied. The tumour, on examination, was found to consist of one large cyst, which had been emptied by the trocar and several smaller ones situated near the attachment of the pedicle; there had been intense congestion throughout with hæmorrhage, especially between the smaller cysts; there was no lymph on the surface. The omentum was inflamed and folded up on itself so as to form a distinct tumour which could not be unravelled, and the right ovary, which was not removed, appeared normal though rather small. Mr. Battle remarked that the difficulty in micturition which had been complained of appeared to be due to traction on a short pedicle by a cyst which had rapidly increased in size when it had escaped out of the pelvis, and that this traction had been increased by the partial rotation of the cyst to the right.

Excision of the Rectum.—The same surgeon operated on a woman, æt. 63, suffering from malignant disease of the rectum of some three or four months' duration. The patient had applied at the hospital for prolapse of the posterior wall of the vagina, but she was transferred to the surgical department for the more serious condition which was then found. The growth extended on the right side of the bowel from the margin of the anus upwards for about three inches, then completely encircled the gut, but did not reach so high up or so low down on the left side; there were hard everted edges, and a ragged and depressed ulcerated surface which bled freely when examined, the base was not adherent to the surrounding parts; no enlarged glands could be felt, nor was there evidence of disease elsewhere. An incision was made from within the anus backwards to the tip of the coccyx, the bleeding vessels were secured, silk loops inserted on each side of the wound to act as retractors, and incisions made on each side of the anus so as to isolate it; the dissection was then carried upwards, great care being exercised in front, as it was thought the peritoneum was probably lower than usual on account of the prolapse of the vaginal wall. The peritoneum was recognised about an inch and a half from the anus, and an attempt made to separate it from the rectum, but it was adherent, and tore easily in front of the finger, so the opening was enlarged, and the separation of the bowel continued at the sides and behind. There was very little bleeding during this part of the operation. The bowel was then pulled down and divided about half-an-inch above the growth, each vessel being secured with catch forceps as it showed itself. After the wound had been washed out with perchloride solution, the opening in the peritoneum was closed with continuous suture; the edge of the bowel was then sutured to the wound in the skin by interrupted sutures of fish gut; the posterior wound was closed in a similar way, excepting for the last inch, through which two drainage tubes were passed, one on each side of the bowel. A large tube with a covering of iodoform gauze was inserted into the rectum so as to convey any fæcal matter which might escape into a dressing independent of the posterior wound. The patient bore the operation well. Mr. Battle said that some nine years ago, he had operated for more extensive disease in a woman of the same age, and that he had found it easy in that case to separate up the peritoneum. This patient, he believed, was still alive; and he had no doubt that the difficulty of separating the peritoneum in the present case was due to changes in its structure as a result of the old-standing prolapse of the posterior vaginal wall.

MIDDLESEX HOSPITAL.

Ovariotomy — Simulated Pregnancy. — Mr. Bland Sutton performed ovariotomy on a woman with the following curious history. She was 40 years of age and the mother of two children, the youngest being 12 years old. Since the birth of this child she had missed a period. In December, 1893, the belly began to enlarge, and at Christmas the patient believed she felt the movements of a child. As the case progressed, the woman, in conjunction with the nurse, calculated from the size of the belly that delivery should take place in April. Everything was arranged for the confinement, but the child did not manifest any signs of appearing, and the patient was confident that she again felt movements of the fœtus. The doctor began to suspect that something was wrong and carefully examined the abdominal swelling, and came to the conclusion that it was probably a tumour. Mr. Bland Sutton was asked to see the case and determined that it was an ovarian tumour; his view was confirmed at a consultation within the hospital. The tumour was a multilocular cyst, with one big loculus predominating. There were no adhesions. The cyst contained twenty pints of fluid. Mr. Sutton remarked that the chief interest in the case was the way in which the rapid growth of the tumour simulated pregnancy. He said he had dealt with two other similar cases. In one an elderly man married a woman of 45, and congratulated himself when, a few months after marriage, he detected an increase in the circumference of the abdomen of his spouse. A year later Mr. Sutton determined the presence of a large ovarian tumour and successfully removed it. He also pointed out that very great care is necessary in some cases to avoid mistaking an ovarian cyst for pregnancy and *vice versâ*.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 6, 1894.

SOME POINTS ON THE LEICESTER SMALL-POX EPIDEMIC.

The last annual report of Dr. Priestley, Medical Officer of Health for Leicester, contains many valuable and suggestive observations upon the late small-pox epidemic. The outbreak was traced to a tramp who, in August, 1892, lodged for a few nights in the workhouse. Since that time the disease has been introduced into the borough by tramps in no less than 11 separate instances, a fact that speaks volumes for the need of stringent supervision of this vagrant section of the community. Altogether 308 cases were notified, and of these 15 died, giving a death-rate of 4·8 per cent. The highly significant fact is added that all the deaths occurred in non-vaccinated persons. A further analysis of the figures shows that a large proportion of the cases occurred in children under ten years of age, an observation which is of special interest when recorded of a town which is a centre and stronghold of the anti-vaccinationists. As to the value of vaccination and re-vaccination, Dr. Priestley remarks that his own faith in its efficacy is well known, and further, to use his own words, "that faith has not been shaken, but, on the contrary, strengthened by what I have seen in dealing with the Leicester small-pox epidemic, not only whilst treating the patients in hospital, but also in dealing with the cases generally in the town (quarantines and others). It will be admitted that I have had exceptional opportunities of judging, having seen every case of small-pox, and having visited every infected house." This evidence has been before the public long enough to place powerful weapons in the hands of all who are called upon to carry on defensive or offensive warfare against the anti-vaccinationists. There is another aspect of the report, however, which is less reassuring to the apostles of public health, inasmuch as it furnishes cogent reasons against the erection of hospitals for infectious diseases in the midst of inhabited quarters. When the epidemic first started in 1892, the Leicester Sanitary Authorities attempted to treat small-pox cases in or near the buildings used for scarlet fever, but with disastrous results. Latterly, the hospital has been reserved for the reception of small-pox patients only. It is situated on a site that is more or less isolated except in one portion, where a strip of vacant land 620 feet across separates it from a district of 660 houses, containing some 3,000 persons. Nearly the whole of these houses would be contained within a circle of 2,000 feet radius, having the hospital for its centre. About the second week in June, 1893, numerous cases of small-pox were notified within this area, which may be regarded as a kind of isolated suburb, and is known by the name of Newfoundpool. Many of these cases, according to the statement of Dr. Priestley, it is impossible to account for except on the assumption that they were infected from the hospital. The medical officer confesses himself unable to point out exactly in what way the contagion was spread. He thinks, however, that probably several causes were at work, which he classifies into—(A) *direct*, through contact between patients and people outside the hospital, and by infection carried out by visitors, members of the staff, &c.; and (B) *indirect*, through the air, which may be (1) the atmosphere, or (2) sewer-gas, *i.e.*, through the drains. But whatever the exact means of infection, there can be little doubt as to the startling nature of the results, a fair idea of which may be gathered from the following extract: "There were in all between Dec. 23, 1892, and Dec. 12, 1893, 55 cases in Newfoundpool, a number which represented thirty-eight infected houses. Of this number of houses sixteen were in the road which was nearest and which ran parallel to the hospital site, and of these sixteen, eleven were on the hospital side of the road. Thus, of 347 cases of small-pox which occurred in Leicester during the recent outbreak, 55 were located in Newfoundpool, giving a case-incidence there of 18·3 per 1,000 of population, as against 1·6 per 1,000 in the remainder of the borough." A further interesting fact was that the hospital proved a more potent source of infection in June than in any other month, and this Dr. Priestley attributes to the prevailing direction of the air currents during that month. With regard to the danger of small-pox hospitals as foci of disease, it may be at once stated that the observation is by no means new. Seldom, however, has it been more forcibly illustrated than in this Leicester experience, which presents an object lesson of the utmost value to sanitary authorities. Obviously the moral to be drawn is that under no circumstances should small-pox wards be allowed to exist within a considerable distance of inhabited dwellings. After a warning of this kind any local body which erects a small-pox hospital within the limits either of town or of suburb must be held responsible for the margin of preventible disease that will almost certainly result from its unwise action. A greater inconvenience is likely to ensue from the fact that inhabitants who object to have a fever hospital located in their district will have their hands greatly strengthened by being able to point to such facts as those recounted by Dr. Priestley. The difficulty of obtaining suitable sites for these establishments is already very great, and authorities all over the country will help to smooth the path of preventive medicine by placing all small-pox hospitals outside their towns.

◆

THE GENERAL MEDICAL COUNCIL AND THE EXAMINATIONS OF THE IRISH "COLLEGE AND HALL."

It will be noted upon perusal of our report that the General Medical Council has declined—for the present—to accede to the entreaties of the Irish and London Colleges of Physicians that they should ask the Privy Council to extinguish the examinations of the Irish College and Hall. The majority of the Council was, no doubt, influenced by a feeling of justice; but, as we judge from the reports, they were also impressed with the idea that it would be a very unwise thing to give the Irish College of Physicians a monopoly of diploma-granting in Ireland, especially in view of the traditionally impractical character of that body. It was suggested by one of the speakers that to restrict Irish educated candidates to a body which insists on keeping up the diploma price to forty-two guineas would be a fatal error, and we entirely agree with this view. Time after time the Irish College of Surgeons has urged upon its sister College the propriety of making a *pro rata* reduction of fee, and has been met, even within the last few months, with a reiteration of the *non possumus* with which the proposal was met on previous occasions. In the interests of justice, of medical education, and of the Irish "College and Hall," however, we almost regret that the apologies of the representatives of those bodies were so profuse, and that the Medical Council did not carry out its threat to appeal to the Privy Council. We say this because we entertain little hope that the respite of twelve months granted to the Apothecaries Hall examinations will have much effect upon the present situation. The examinations will be inspected and reinspected, and repeated official reports will be published; but, unless a change takes place in the policy of the wire-pullers of the General Medical Council, we know, beforehand, that these reports will be more and more condemnatory, and this time next year the Irish College and "Hall" will have to meet the Irish College of Physicians at the bar of the Privy Council. The dictates of truth and justice compel us to state—whether our doing so offends the General Medical Council or not—that the recent inspections of these examinations were carried out in a spirit not of honest criticism, but of captiousness and fault-finding, and that the system was pre-doomed to condemnation before the Examiners met at all. We should be sorry to suggest anything but honesty of intent in either of the Visitors; but we declare that to send a high officer of the prosecuting College, and a gentleman from England who has distinguished his inspectorial reports by a uniform depreciation of everything medically Irish, to nominate such judges to pass verdicts on the Irish Apothecaries' scheme, was to ensure conviction and condemnation. The reports carry this fact "writ large" across their pages. The first report undoubtedly hit palpable blots in the examination, the reality of which the Irish College and Hall were the first to acknowledge and to remedy; but it was also largely occupied with captious criticisms of petty details which could scarcely have been discovered without diligent search, and which, if all the criticisms were just, would not materially prejudice the efficiency of the scheme. The second report, inasmuch as the substantial blots had been erased, was limited to the latter form of criticism, and the Visitors were fain to give substance to their condemnation by placarding the ignorance of the candidates, which the Examiners had fully recognised by peremptory rejection. We speak with intimate knowledge when we assert that the examinations condemned by the Visitors were conducted with painfully careful regularity, and, if conducted by any other Examining Board in the kingdom, would have received at least a modified approval, and we will add that there is not an examination in the kingdom which would have "'scaped whipping" if submitted to the ordeal of hostile search to which these examinations were subjected. If it be considered presumptuous in us to place our word against that of the General Medical Council, we plead that that body has no source of information whatever—at least, none that sees the light—save the statement of the Visitors, which it seems to have accepted with an alacrity which looks like prejudice. It must be, indeed, manifest to anyone who reads between the lines the reports of the Examination Committee and the Education Committee of the Council, and the debates thereon, that a vigorous attempt has been made by these Committees to persuade the Council to do the work of the Irish College of Physicians by extinguishing that scheme. The fact that at the previous meeting of the Council condemnation was passed and ostentatiously published without affording the Irish College and Hall the opportunity of seeing the accusations or giving an answer, affords conclusive proof that the destruction of Carthage had been resolved upon. Corroboration is now afforded by the fact that the defences offered by the Irish College and Hall have been totally ignored in the reports of these Committees, and, lastly, the purpose of this onslaught on the examinations is admitted to be, not the improvement or perfection of the system, but its total extinction. "The Committee think it very desirable that the General Medical Council should suggest to the Royal College of Surgeons in Ireland the propriety of severing their connection with the 'Hall.' The Committee is of opinion . . . that the continuance of that combination in Dublin is no longer desirable . . . Two Universities and two Royal Colleges can certainly supply sufficient qualifications for the requirements of practitioners in Ireland." Recollecting that the sole duty of the General Medical Council is limited to making examinations perfect, and that the Council itself approved of the establishment of this Conjoint Scheme, we are tempted to ask whether it is not the Irish College of Physicians that speaks these words. For ourselves, we say that, having no interest whatever in the continuance of these Conjoint Examinations, and being in perfect sympathy with every honest effort of the General Medical Council to make these examinations perfect, we cannot stand by in silence and see the drama of "The Wolf and the Lamb" brought to its conventional conclusion. If the Irish College of Physicians wants to get the Irish Apothecaries Hall out of its way it can do so by more ready and more honourable means than by trumping up charges and exercising influence in the General Medical Council.

DENTAL ETHICS AT THE GENERAL MEDICAL COUNCIL.

It seems to be still a moot question whether or not the dentists on being raised to professional status did or did not forfeit their right to advertise. The difficulty arises, of course, only in respect of dental practitioners admitted to registration in virtue of their rights at the date of the passing of the Act. So far the dentists have been divided into two very distinct classes, viz., those who practise in virtue of a diploma, one of the conditions of which is that they bind themselves to abstain from advertising under penalty of forfeiture, and, secondly, those who are admitted to registration on the ground of their practising, or of having commenced the study of, dentistry previously to the passing of the Act. The resolution passed by the General Medical Council at the end of the session which has just terminated does not in the least help to put matters straight, nor does it tend to place the two classes of dentists on the same footing in this respect. Indeed, it may fairly be construed to legalise advertising of a kind, that is to say, advertisements which do not comprise claims of superiority over other practitioners, and this admission is decidedly a retrograde step. It exhibits, indeed, a curious want of logic. Either dentists may advertise or they may not. If not, why should one class be allowed an advantage which is denied to the other? Taken as a whole, the resolution, which will be found in our report of the Council's proceedings, is likely to be productive of more harm than good, for the reason that it inferentially admits the legality of self-advertisement under certain restrictions. We trust the Council will studiously avoid any such ambiguity in respect of medical practitioners, for the result would be extremely detrimental to the status of the profession. It would be a good thing if the Council could be induced to recognise once and for all that its mandate is peremptory and not advisory; in fact, that it is for the Council to lay down the law and not to discuss it. No earthly good can result from resolutions condemning in advance advertisements of an "objectionable" character. What is objectionable? Opinions, even on the Council, differ very widely on such a point, and advertising dentists can hardly be expected to find out for themselves, except at their cost, what precise ethical standard the Council is prepared to enforce. A few will have to be executed, professionally, *pour encourager les autres*, and then, after a time, the Council and the dental practitioners will understand each other. This question of "objectionable" advertisements, the most important detail of the resolution, is left deliciously vague, and we doubt very much whether the Council will have the courage to mete out justice on the strength of such a vague and indefinite declaration. It is necessary to guard against the tendency to listen to individual claims to mercy in the consideration of penal cases, for it often happens that too little attention is given to the wrong inflicted upon the public and the profession. We are willing enough to welcome dentists to the fold on condition that they fully and completely comply with our code of ethics, but otherwise they must remain with us but not of us. It will be for the Dental Association to take steps to bring the resolutions affecting dental practice into line with those regulating the practice of medicine.

◆

Notes on Current Topics.

The Operating Theatre Connected with the Martha Ward at St. Bartholomew's Hospital.

In the "Operating Theatres" of our last week's issue, an operation was reported which was done in the theatre connected with the Women's Ward at St. Bartholomew's Hospital; it may be as well to point out the really admirable arrangements which exist in this theatre for the welfare of patients undergoing abdominal section. The theatre, which is always prepared by being thoroughly ventilated and cleaned, is nearly square, and is well lighted by windows south and east and by a lantern skylight; it is heated by hot water coils and by a fireplace, hot and cold water are laid on to a marble washing basin, the wastepipe of which discharges into the open air, so that sewer contamination is impossible. The operating table is made of a light framework of polished brass, the top consisting of a shallow copper tray forming a hot water reservoir, over which there is an inch thick plate glass slab; upon this last is laid a narrow perfectly clean folded blanket on which the patient is placed, the reservoir having been previously filled with water at a temperature of 130°. Fitted to slide along the table is a plate glass tray 12 inches wide and the same length as the width of the table; this, supported by four uprights, fits over the patient's knees, the supports resting on a projecting slot which enables the tray to be slid backwards and forwards; it is very handy for the sponge bowl and for the instruments in actual use. The tables for the dressings and instruments are of plate glass on metal supports, the one for the latter being semi-circular, fitting, as it were, round the surgeon, bringing all the instruments within reach, and keeping off too zealous spectators. There are three sterilisers fixed in the theatre made of fine polished copper, one for the water, one for the instruments, and the third for the dressings. The instruments are made to take to pieces and are thickly nickel-plated except the cutting edges; they are kept in an absolutely air-tight case. The sponges and forceps are always counted out loud before the operation and their number written down on a blackboard, they are again counted before closing the wound. All water to be used at the operation is boiled.

Blood-Poisoning in Workshops.

An inquest recently held at Wolverhampton in regard to the death of an ironworker who had contracted blood-poisoning at his work revealed some facts to which it is only right that public attention should be drawn. The main facts of the case were as follows: The patient, a man aged thirty, while following his occupation had his foot burnt by a cinder, and two days later his trousers caught fire. In order to extinguish the flames, he placed his leg in some water. Subsequently, however, he began to complain of pain in the leg, and he was accordingly removed to the hospital, where, after a few days, he died of acute septicæmia. In the course of the evidence, it transpired that the water used in the ironworks in which the deceased was employed was obtained from an adjoining canal. Under the circumstances, therefore, it is not surprising that the man should have contracted blood-poisoning in view of the fact that he bathed a wound of his leg with water which could hardly have been less than diluted sewage. The facts adduced at this inquest should undoubtedly be brought under the notice of the masters of the ironworks throughout the Kingdom. That a workman should have lost his life in the manner above narrated is a sad reflection upon the principles of sanitary science of the present age. Even supposing that no direct harm happened to the workman by coming in contact with foul water in the workshop, is it supposed that such foul water does not continually give off poisonous effluvia, especially when its temperature is raised by plunging hot metal into it? Clearly this is a matter into which inquiry should be made by the sanitary authorities of the districts in which ironworks are located, and notices should be placed in the works warning the men against using the water for any other purpose than that to which it is usually applied. Moreover, if the men are exposed to any risks by which their clothing is apt to catch fire, requiring water to extinguish the flames, a set of rules should be drawn up and other precautions adopted by which the necessity for resorting, as the only alternative, to a tank of foul water would be avoided.

Vaccination and Cancer.

We are glad to see that Mr. Lawson Tait, in the columns of the *Birmingham Gazette*, has exposed the fallacy upon which the anti-vaccination faddists lay so much stress, that vaccination is responsible for the dissemination of cancer. Some person appears to have written to our contemporary—we have not seen the letter—claiming that the increase of cancer was due to vaccination, and basing on this false supposition a series of equally false inferences, which are well disposed of in Mr. Tait's letter. In the latter the following sentence appears: "I could burden your columns with a large number of facts which are absolutely inconsistent with Mr. Williamson's views, and my own belief is that vaccination has no more to do with cancer than has the eating of tomatoes. I mention the latter theory, for scarcely a month of my life passes in which I am not appealed to as the author of this absurd conjecture." The medical profession—it may be said—generally has not been able to congratulate Mr. Tait on his public utterances so far as the vivisection controversy is concerned, but in this instance he has certainly done good service in exposing the wiles of an ignorant anti-vaccinationist. So much nonsense and so many perversions of truth are published in the newspapers which trust to increasing their circulation by adopting popular fallacies, opposed to the true teaching of medical science, that any medical man of standing, who runs the risk of professional criticism by sending communications to the offending journals refuting the pernicious statements, is undoubtedly worthy of commendation.

Dental Caries and Cervical Abscess in Children.

At a meeting of the Odontological Society on Monday evening last, Mr. Edmund Owen opened a discussion on the treatment of carious milk molars. He gave it as his opinion that the conservative treatment was being carried too far; that many such teeth were stopped which ought to be extracted. He said that it was worse than useless to prepare and stop a temporary molar whilst septic micro-organisms were left lurking about the fang, for in due course these germs found their way into the cervical lymphatic glands, and produced suppuration. He held that if a tooth were far advanced in caries it was practically impossible to render it aseptic, as children could not submit to the necessary manipulation and restraint. He strongly condemned the method of treatment of "capping" a carious tooth and leaving the elements of disease uninterfered with. A brisk discussion ensued; and though it was evident that Mr. Owen's views did not receive universal assent, it is not unlikely that good will result from the ventilation of the subject. It is beyond question that dental caries is a very common cause of glandular abscess in children, and the more general the view which the dental specialist takes of the question the better. It is quite possible to carry conservatism too far in dental surgery as elsewhere.

Prosecutions by the Pharmaceutical Society.

The Council of the Pharmaceutical Society have for some time now been on the warpath against the unauthorised sellers of poisons, and some signal victories in connection therewith have been gained. The spirited action of the Society in undertaking the prosecution of the persons dealing in quack nostrums of a poisonous nature has, however, in some cases not been successful, and the necessity of an appeal has thus arisen. One such case has, nevertheless, we are glad to see, just been declared in favour of the Society. It was that of a watchmaker who sold a preparation containing perchloride of mercury. But the County Court Judge before whom the action was first tried, held that there was no case for a conviction, under the Acts, because the shop did not disclose externally that poisons were sold within. The Society, however, appealed against this decision, and the appeal was allowed with costs at each Court, on the grounds, as stated by Mr. Justice Cave, that the defendant used the shop for the sale of poisons, and that anybody was at liberty to go in and purchase his preparations. The action in question must have proved a somewhat costly matter to the enterprising watchmaker, who, saving for the Society, might have still been selling broadcast quantities of poison to the public in his neighbourhood.

Fish Poisoning.

Two cases of fatal gastro-enteritis following the eating of fish have been reported during the last week. The first was that of a young Birmingham woman, who was seized with sickness and violent pains shortly after eating some smoked haddock in a raw state. Her death illustrates the fallacy of the popular notion that it is safe to eat uncooked cured fish, and the warning should prove useful when one reflects how much of that particular article of diet is daily consumed. Curiously enough, the Jews, who are usually sound in their gastronomic habits, indulge greatly in the delicacy in question. The second case, reported from Gloucestershire, is a much commoner kind of fish poisoning. It appears that a woman bought some mackerel, of which she and two children partook. Two days after one of the children, a boy of four, was taken ill with vomiting and diarrhœa, which soon after proved fatal. It is a pity that the subject of mackerel poisoning has not been scientifically investigated, so as to ascertain the exact conditions under which the fish becomes dangerous. Exact knowledge on these points would probably prevent a large proportion of the deaths from the consumption of mackerel reported every year.

Thyroid Extract in Skin Diseases.

At the first annual meeting of the new Dermatological Society, an interesting paper was read by Dr. Byrom Bramwell on the action of thyroid gland in skin diseases. Since his first communication on the subject at the British Medical Association last year, he has gained a large amount of additional experience as to the handling of this powerful drug. He states that it is not uncommon for a fresh crop of spots to appear in treating psoriasis, but that the fresh eruption is ill developed and comparatively short lived. He pushes the administration of the remedy until "thyroidine" is attained, and in some instances gives the enormous dose of thirty or forty-five grain tabloids daily. As announced in his original paper, the best results have been obtained in psoriasis. Lupus appears to derive benefit up to a certain point, and then to relapse. One case of ichthyosis, in which the remarkable improvement took place under thyroid treatment, was shown in a series of photographs demonstrated by a lime-light lantern. Altogether, the added experience of Dr. Bramwell appears to confirm the first impression that in thyroid gland we have a potent weapon against many diseases of the skin.

Cholera in India.

M. Haffkine will now be able to fully test the value of his inoculation treatment in India. The disease has at present assumed an epidemic form at Chittagong, and already the deaths of five Europeans have in consequence resulted. As soon as the outbreak occurred, M. Haffkine was communicated with, with a view to the inoculation of as many of the community as felt inclined to submit to the preventive procedure. About a thousand persons were soon inoculated, including almost all the officials, their wives, and other European residents, also a large number of the coolies. So far, no information has reached us respecting M. Haffkine's results, or whether the European community which has submitted to the treatment has had reasons for being satisfied that any immunity from the disease has been derived. These are matters into which one or other of our Indian contemporaries might make it its business to inquire within the next few weeks. The facts collected in connection therewith would be sufficient, probably, to make an interesting report.

The Testimonial to Sir George Buchanan.

In accordance with Sir George Buchanan's wish, the money raised to commemorate his services while Medical Officer to the Local Government Board, has been devoted to the foundation of a gold medal of the value of twenty guineas, to be awarded by the Royal Society every three or five years in respect of distinguished services to hygienic science or practice in the direction either of original research or of professional, administrative, or constructive work. The medal shows Sir George's portrait on the one side, and an allegorical group on the other. The presentation ceremony took place at Dr. Bristowe's house last week. The die, it was stated, together with £276 12s., had been handed over to the Royal Society. The first Buchanan Gold Medal was then presented to Lady Buchanan, and a bronze medal, together with the book containing the names of the subscribers, was handed to Sir George.

Suicide by Deputy.

A curious case, possessing a certain medico-legal interest, was tried at Marseilles, the accused being a lad, only 16 years of age. He was arraigned on a charge of murder, the victim being an elderly man with whom the prisoner was known to be on intimate terms. It transpired that the victim was suffering from an incurable malady and was desirous of putting an end to an existence which afforded him little joy, and threatened in the near future to become an intolerable burden. His physical courage, however, was not equal to the carrying out of the fatal project, and at this juncture he sought to secure the assistance of the lad in question, in return for the payment of a comparatively large sum of money. The documentary evidence left no doubt as to the authenticity of this version, and although the law does not recognise the validity of any such delegation of lethal powers, the jury—influenced possibly by the fact that suicide, in France, is not accounted a crime—could not find it in their hearts to condemn the deputy suicide, and contented themselves with confining him in a reformatory until his majority. A very different fate would have been his lot in this country, and careful anthropometric observation may possibly justify the conclusion that this precocious youth might have been sacrificed to the outraged majesty of the law without detriment to society at large.

Offence against the Rabies Act.

The provisions of the Rabies Act have been carefully framed with a view to safeguarding the vital interests of the community. One of them directs that cases occurring in animals must be at once reported by owners to the local authorities. The neglect of this particular duty has lately led to the conviction of a gentleman in the Birkenhead Police-court. It appears that he destroyed two dogs that became afflicted with rabies, but by omitting to notify the police of the occurrence he committed a technical offence for which he was very properly fined by the magistrates. The defendant pleaded ignorance of the law, a defence which is, of course, powerless to excuse non-compliance with legal enactments. In commenting on this case one of the local newspapers suggests that it would have been more in the interests of the town if the matter had not been brought into the police-courts. By a simple extension of that argument it would be better for all watering places to draw a veil of discreet silence over any such little unpleasantness as an outbreak of diphtheria, of typhoid, or of small-pox. Fortunately, however, for the safety of seaside visitors the omniscience of modern journalism and the enlightenment of improved sanitary methods render such catchpenny and selfish reticence impossible.

The Medical Defence Union.

The original dispute between members which has led to so much subsequent commotion has ended in an unlooked-for way. Last week it was announced that the consolidated actions between Drs. Collie and Bloxham had been arranged out of court, each party withdrawing imputations against the other. This unexpected termination places the Council of the Society in a somewhat awkward dilemma. The Council took up Dr. Collie's case, and defended their action when questioned by several members of the Union on the ground that there were "exceptional circumstances" to justify them in doing so. When Dr. Bloxham brought his action for undue maintenance against the Society, the Council lost the case rather than disclose the "exceptional circumstances." The costs of the action, several hundreds of pounds, will, we understand, have to be defrayed by the Union. We shall await with interest the Council's declaration of the "exceptional circumstances," which have now been abandoned by Dr. Collie, the complainant, who brought them forward in the first instance.

Insanitary Bakehouses.

The Local Government Board has caused a circular to be issued in which it calls attention to the responsibilities and duties of the sanitary authorities with reference to the London bakehouses. It invites not only periodical inspection but reports of cases of non-compliance with the statutory provisions of the Health Act with the view of ulterior proceedings against those who persistently set the law at defiance. The sickening details of the conditions under which much of the bread making is carried on is fresh in the public mind. It is likewise probably well known to the owners of these insanitary places that the magistrates have power to inflict upon them a choice of punishments—varying in severity. Why should there, then, be any hesitation on the part of local authorities in the matter? The circular imposes no new regulations, but merely reminds authorities that the existing law is sufficient for the purpose of closing the filthy dens to which officers of health have repeatedly called attention. To what end does the sanitary inspector draw attention to a heap of garbage, which emits a foul stench to the sickened senses, and is seen to be a fruitful nidus of disease, if it fails to move the constituted authority to take immediate action for its suppression or removal?

A Leprosy Commission to Iceland.

A new Commission has been appointed. It is to consist of medical men, who will be sent out at the cost of the Danish Government to study the disease in Iceland. The date of its departure is fixed for the 6th of July next, and the vote for the necessary funds has been formally passed by the Danish Assembly. Amongst the members of the Commission will be Dr. Eichmuller, of Paris, and Dr. Neisser, of Paris. So much interest has been aroused during late years as to the etiology and pathology of this interesting disease that an event of this nature cannot fail to excite considerable attention in scientific circles. Fortunately leprosy as an endemic affection has disappeared from Great Britain. In Iceland, however, it is still prevalent, and late statistics reported the existence of fifty lepers upon the island, although it is believed in many quarters that in reality the number is greater. Iceland is fairly accessible from our own country, and any enthusiastic student of leprosy would doubtless find himself well repaid for his trouble were he to pay a visit to a place that is interesting on other than purely scientific grounds.

Outbreak of Small-pox in Dublin.

We regret to announce the occurrence of eight cases of small-pox under circumstances which inspire alarm as to a possible extension of the disease. A man was admitted to the Hardwicke Fever Hospital with well-developed variola, and immediately afterwards it became known that the disease had attacked four patients in the North Dublin Workhouse, which is quite close to the hospital. On inquiry it was ascertained that the original patient had been in the workhouse as a casual a few days previously, and it is assumed that he communicated the disease to the inmates. Up to Sunday last eight victims had been stricken, but the occurrence of the zymotic in an institution like the North Dublin can hardly be expected to stop there. Needless to say, Sir Charles Cameron, the Executive Officer of Health of the city, and all the Medical Officers of the Union have adopted the strictest means to prevent the spread of the epidemic.

Evanescent Prescriptions.

The unfair use made of prescriptions by the public has over and over again been made the subject of complaint, but so far no practical suggestion has been made whereby the physician would be enabled to restrict the use of the prescription to the persons and to the particular ailments for whom or for which it was originally given. It must have occurred to many practitioners that it would be a great boon if it were possible to arrange matters so that a prescription should become invisible at the expiration of the period for which it was ordered. An ingenious correspondent suggests that this might be achieved, in a certain measure, by writing the prescription in an ink composed of iodide of starch. This can be prepared at will with the greatest ease, and the coloured fluid thus obtained has the property of becoming invisible after the lapse of a sufficient period of time to allow of the evaporation of the iodine. We give the suggestion for what it is worth without being over sanguine as to its practical value.

A Difference.

A short while ago a member of the Royal Family while shooting at Windsor, was unfortunate enough to receive a shot-corn in his eyeball. A great authority in ophthalmic surgery, though a general surgeon, was sent for, and he promptly removed the eye-ball. But so quietly did the affair pass off, that even members of the profession were asking who the surgeon was. When they heard, they knew that everything had been done well. A well-known politician has cataract. Far and wide it becomes known who is looking after him, and even what the specialist thinks of the progress of maturation of the cataract. An account is given of the way in which the operation was borne, and also the name of the assistant who sponged the wound. We are of opinion that the course adopted by the surgeon in the former case is to be preferred.

Suppression of a Medical Officer's Report.

A curious affair has come to light in the management of the public business of the Lambeth Vestry. An epidemic of enteric fever has lately prevailed in the district, and a report dealing with the occurrence was duly sent in to the Sanitary Committee. By a majority vote of seven to six, however, that body decided not to bring the matter before the notice of the Vestry. This attempt at reticence was checkmated a little later on by the publication of the complaint of a neighbouring parish that it was unable to get a copy of the report of the Medical Officer of Lambeth on the late outbreak of enteric fever. Several members of the Lambeth Vestry took the matter up, and a motion directing the sub-committee to forthwith furnish the report was unanimously agreed to. It certainly seems an unwise step to try and hush up the existence of a serious epidemic in the midst of a populous community, more especially when the source of infection lies, as in this case, in a contaminated milk supply. It is to be feared that the reluctance to interfere with vested interests unduly influenced members of the Lambeth Sanitary Board. We trust that there are few Health Committees in this country that would attempt to hoodwink their constituents in so unwise a manner.

A Half-Sovereign in the Left Bronchus.

A curious case of death from the lodgment of a coin in the lower air passages has been lately reported from Carlisle Gaol. It appears that a convict had been sentenced in that town for stealing a purse which contained a half-sovereign. He swallowed the coin in question, which found its way to the "bottom of the left lung," and caused fatal hæmorrhage. This interesting item of criminal jurisprudence is by no means unique. Several cases are on record in which coins swallowed by thieves have become lodged in the larynx or one of the bronchi. In a lecture some years ago Mr. Bernard Pitts related a case of the kind in which a pedlar swallowed a small sham ornament, which, so far as we remember, was ultimately removed after a prolonged sojourn in the air passages.

Infectious Diseases Among Tramps.

The Outdoor Relief Committee of the St. Pancras Guardians, at a meeting of the board last week, recommended that the medical officer of the workhouse be specially engaged for three months to examine all persons admitted to the casual wards of the parish. It was pointed out that the guardians had information in their possession which showed that infectious diseases were spread by vagrants, and fully warranted the step proposed, particularly with the prospect of a small-pox epidemic. When a similar precautionary measure was taken a few months since, several persons seeking admittance to the wards were found to be suffering from small-pox. The motion was unanimously agreed to.

The Approaching Accouchement of H.R.H. the Duchess of York.

The arrangements in connection with the approaching accouchement of Her Royal Highness the Duchess of York have now been completed. It has been decided that the accouchement shall take place at the White Lodge, Richmond Park, the home of her mother, the Duchess of Teck, and for this purpose the Duchess of York is now on a visit at the White Lodge. The services, we understand, of Dr. John Williams have been engaged for the occasion, and from the 12th inst. he will be in attendance on Her Royal Highness. In common with all the loyal subjects of this realm, we can only express the hope that all will be well, and that Her Royal Highness will make a speedy and safe recovery.

The Prevention of Cruelty to Children.

It is greatly to be regretted that this much-needed philanthropic measure for the amelioration of the condition of our little ones should have been *talked out* in the House of Commons on Wednesday last! There was no reason for spending a whole morning debating the report stage of a bill which everybody approved. The sacrifice was deliberately made and solely for party purposes. Thus the chances of passing a purely beneficial measure were deliberately flung away, and the Act for further prevention of cruelty to children has thereby been indefinitely postponed.

The Burton Infirmary, through Mr. W. H. Worthington, has just benefited to the extent of £10,000. The donor, who is principal member of the well-known brewing firm, imposes the condition that the money shall be invested in debentures or preference stock of some first-rate railway company, and that the dividends shall be used for ever towards the maintenance of the institution. It is to be kept separate from the other investments, and the capital amount must never be used.

We have to record the death of Dr. Turner, at the age of 63, an old medical practitioner of Ryde, which took place on Saturday afternoon last, at his residence, Barfield. Deceased had been in practice in Ryde 30 years, having succeeded his uncle, Dr. Mark Brown.

The annual collections in aid of the Metropolitan Hospital Sunday Fund take place on Sunday next.

Special Articles.

MODERN VIEWS ON COD-LIVER OIL.

Many of our physiologists claim that cod-liver oil is the most readily assimilated fat known, to which belief they attribute its value in treating disease. Scientific research often corrects erroneous theories and beliefs. The results of the French investigators in isolating and determining by clinical work the physiological action of the individual active principles of cod-liver oil is a decided advance in pharmacy, and we believe will be welcomed by the most conservative of medical men.

The discoveries of the composition of cod-liver oil have developed gradually. For a long time, we were content with the statements that it contained oleic, palmitic and stearic acids, with glycerine, butyric acid, various biliary principles, iodine, phosphorus, and traces of bromine; following these, gaduin and propylamin were reported.

Gradually the work has gone on until it is settled beyond doubt that cod-liver oil contains certain specific principles peculiar to itself which are not present in other fats or oils, to which it owes its medicinal value, and not to the long held theory of its being the most readily assimilated oil or fat known. Furthermore, these specific principles can be removed from cod-liver oil, retaining their full activity, and administered to patients, either alone or dissolved in a palatable vehicle, such as wine.

We do not wish to go into an exhaustive report of the methods employed for extracting the true active principles from cod-liver oil, but will present briefly the substance of the reports of the French investigators on the active principles of cod-liver oil and their therapeutic properties.

M. Gautier and L. Mourgues, of Paris, after giving cod-liver oil an exhaustive series of analytica researches covering a period of several years, were successful in isolating certain alkaloidal and other active principles, the most important of which have hitherto been unknown. These principles were tested clinically on animals. The following is a short abstract of Gautier and Mourgues' exhaustive paper:—

The total amount of mixed basic extractive matter obtained from cod-liver oil gave, by successive distillation, the following constituents:—

1. Butylamine, amounting approximately to one-sixth of the total bases.
2. Amylamine, constituting one-third of the whole.
3. Hexylamine, a small amount.
4. Dihydrotoluidine, forming about one-tenth of the total alkaloids.

Fixed bases:—

1. Aselline.
2. Morrhuine, constituting about one-third of the total alkaloids of the oil. This substance, the authors consider to be one of the most efficacious principles in cod-liver oil.

Besides the volatile and basic substances, Messrs. Gautier and Mourgues separated several other acids previously combined with the bases:—

1. Morrhuic acid.
2. A mixture of formic and butyric acids.
3. A small proportion of phosphoric acid, derived from the phosphates, phosphoglycerates, and lecythines of the extracts.

We now come to the more important consideration, viz., the properties of these constituents. Butylamine, hexylamine, and particularly amylamine increase the urinary secretions. Dihydrotoluidine is a convulsivant toxic base. Aselline in sufficient doses produces dyspnœa, stupor, convulsive disturbances, and, if continued, death. Morrhuine, the most important of the extractive principles of cod-liver oil, is a powerful stimulant of the functions of nutrition and assimilation, promoting metabolic changes; it produces a rapid circulation of the extractive residues of cell life towards the excretory organs, where they are eliminated, provoking in their way indirectly a powerful movement of assimilation (anabolism) correlative of the losses consequent upon the inverse movement of de-assimilation (katabolism). This is considered to be proved by the super-excitation of appetite in animals brought under its influence.

The phosphorus contained in cod-liver oil is by no means all combined in the form of lecithines, and since it is not fully saturated with oxygen and constitutes part of a complex organic molecule, there can be no doubt that it is essentially assimilable and suitable to the recuperation of tissue.

Under the nfliuence of morrhuic acid—(corresponding to what previous experimenters have designated under the name of gaduin)—the urine of guinea pigs, usually scanty and turbid, augments considerably in quantity, and rapidly becomes clear; at the same time the animal attacks food with avidity. These characteristics show, in the authors' opinion, that morrhuic acid, like morrhuine excites the assimilatory functions and the appetite. Morrhuic acid occurs in cod-liver oil to the amount of upwards of a gram per litre (1·54 per cent.). It would appear, therefore, to be one of the most important factors in the efficacy of the oil.

As a summary: The physiological experiments carried on by MM. Gautier and Mourgues demonstrated that cod-liver oil is a reconstituent of the tissues through its richness in phosphates, phospho-glyceric acid, and organically combined phosphorus. Bromine and iodine, which are present in small quantities, also contribute to the reparative action, but chiefly to the active principles butylamine, amylamine, and especially morrhuine and morrhuic acid does the oil owe its true medicinal value.

M. J. Bouillot (abstract of thesis read at the French Academie des Sciences, November 15th, 1892) after an exhaustive series of careful clinical experiments ascertained that the combined active principles of cod-liver oil, given as a medicinal unit, in doses of 15 to 25 centigrammes ($2^1/_3$ to $3^4/_5$ grains) have a distinct diuretic action, increasing not only the quantity of urine but of urea; that they acted as powerful stimulants to the intra-organic oxidation, the oxidation of the leucomaines being greatly facilitated and the toxicity of these bodies diminished. His clinical work confirmed the report of Gautier and Mourgues that the combined active principles of cod-liver oil act as powerful stimulants of nutrition and assimilation, and show definitely the nature of the principles to which the oil to a very great extent owes its medicinal properties.

In his paper M. Bouillot says he believes in place of cod-liver oil its combined active principles will sooner or later be dispensed by the pharmacist as the alkaloids of plants are now used in place of the crude drug.

L. J. de Jongh, M.D., of the Hague, one of the best fitted and most exhaustive writers on the value of cod-liver oil in the treatment of disease, as far back as 1840, did not value the oil as a nutrient, but recognised in it certain therapeutic effects not produced by other oils. We give his view briefly in his own words: "The first apparent advantage resulting from the use of cod-liver oil is always an improvement in the chylopoetic and reproductive system, a decided improvement in the nourishment of the body, as well as an increase in the biliary secretions. Cod-liver oil does not act directly in affording nourishment, as many erroneously suppose, but only indirectly by the promotion of chylopoesis." De Jongh also recognised the alterative and diaphoretic properties of the oil. He was always in doubt, however, as to what part of cod-liver oil it specially owed its virtues.

It is reported by Dr. Doremberg (in *Deutsche Medicinische Wochenschrift*, Nov. 14th, 1889, p. 955) that he has established experimentally that in animals in which tuberculosis has been artificially produced, the disease runs a more rapid course if glycogen be introduced into the system, either subcutaneously or with the food. A weakening of the action of the glycogen attends the administration of cod-liver oil in cases where the tubercle poison has been injected into the animal subcutaneously. The oil does not appear to exercise any influence upon the poison itself, its action appears rather to consist in increasing the animal's power of resistance. This fact may serve in some measure to explain the mode of action of cod-liver oil when given to consumptive patients. Glycogen is a normal product of the liver, always present in more or less noticeable amount in the blood, and increasing by its presence the activity of the tubercular process. Cod-liver oil retarding the pathological evolution of the disease cannot but prove beneficial in this class of cases.

In the above report by Dr. Doremberg he attributes the value of cod-liver oil in treating tuberculosis to its property of increasing the animal's power of resistance, which property resides in the active principles, not in the fatty matter, of cod-liver oil.

According to Chaneaud the extractive matter of cod-liver oil favours anabolic changes, securing more complete assimilation and utilisation of the food ingested, thus coming under the class of medicinal agents to which Prof. Gubler, of Paris, gave the name of Euphoric medicines, which makes a patient bear up well by increasing the organic resistance.

Germain Sée, the well-known professor of clinical medicine in the Hôtel-Dieu Hospital, Paris, in his work, "Le Regime Alimentaire des Malades," recommends the combined active principles of cod-liver oil as being readily retained and easy of assimilation. The therapeutic properties of the extract, he says resemble those of the oil and has, moreover, the decided advantage of rendering assimilable the food ingested with it.

Lafage (*Merck's Bulletin*) has given extensive study to the action of the combined active principles of cod-liver oil in the Paris hospitals. He reports that he found these principles to produce marked improvement in pulmonary catarrhs, in scrofula and certain conditions of tuberculosis, and particularly noted the action of these principles in producing a very decided increase of the patient's strength and return of appetite.

Detailed reports of careful clinical studies of the active principles of cod-liver oil have been published by Dr. E. Locksy, of Paris, and other eminent French physicians, which confirm the work of MM. Gautier and Mourgues, and emphasises the fact that cod-liver oil owes its value as a medicine to its active principles.

In referring to conditions influencing the prognosis of consumption, Dr. I. Burney Yeo (Professor of Clinical Therapeutics in King's College Hospital, London) in the *British Medical Journal* for January 16, 1892, says :—"There is a most essential condition of cure, and without it most of our therapeutic effects will end in failure, and that is a sound organic state, and a sustained functional activity of the organs of digestion and assimilation. The phthisical patient, who cannot digest and assimilate nourishment is in the greatest peril."

This condition, as already stated at some length, is relieved by the active principles of cod-liver oil, which are powerful stimulants of nutrition and assimilation.

◆

THE COUNCIL ELECTION AT THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

The annual election of President, Vice-President, and Council took place on Monday last. The outgoing members of Council all offered themselves for re-election excepting Dr. Kidd, who retires, and Mr. Myles, who has become an Examiner. The outgoing President, Mr. Hamilton, did not seek a seat on the Council, so that there were two natural vacancies in that body besides such others as competition might create. For Council seats the following Fellows offered themselves in addition to the outgoing Councillors :—Dr. Archibald H. Jacob, Mr. Purefoy, Dr. Cranny, Mr. Sherlock, Dr. Auchinleck, Mr. Thompson, of Omagh ; Dr. Harrison Scott, and Mr. Arthur Chance. The ballot resulted in the return of Dr. Jacob, who scored 131 votes, and Mr. Chance, with 113 votes. The poll was headed by Sir Charles Cameron with 153 votes, and Dr. Meldon was next with 150, and the candidate who was nearest success was Mr. Sherlock with 107 votes. The lowest score was 35. As we stated last week, Mr. Thornley Stoker, the Vice-President, becomes President, Mr. William Morrison, Vice-President, and Sir Charles Cameron, Secretary of the College, all without contest.

THE IRISH MEDICAL ASSOCIATION MEETING

Was held at the Royal College of Surgeons in Ireland, on Monday, and was influentially attended. The chair was occupied at first by Dr. Meldon, the outgoing President, and afterwards by Dr. Hercules MacDonnell, of Dundalk, the newly-elected successor to the chair. An animated discussion took place upon the matter contained in the Annual Report of the Council and upon the various resolutions recommended for the consideration of the meeting. The late hour at which the proceedings terminated precludes us from publishing the report or the resolutions this week.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Notification in Edinburgh and Leith.—The close juxtaposition of Edinburgh and Leith, of which the first practises compulsory notification of infectious diseases, the second only voluntary notification, should be of use in comparing the advantages of the two systems. And if there is anything to be deduced from the fact that epidemics of infectious diseases have been more severe and longer protracted in Leith than in Edinburgh, then compulsory notification is of benefit. Against any comparison, however, it can be pleaded, that whereas Leith is placed in a low-lying neighbourhood, Edinburgh is situated in an elevated, healthy position and minus the miserable slums inseparable from ports to which also sailors of every nationality resort. Small-pox has now been existent in Leith for several months, and instead of abating seems to be steadily increasing, the number of cases reported the week before last, 61, being equal to more than 200 in Edinburgh and 500 in Glasgow, if their proportional population be taken into account. In Edinburgh, the disease has only made headway within the last week or two and then only in parts of the city conterminous and in direct communication with Leith. The Edinburgh Town Council, last week, went so far as to remonstrate with the Leith authorities, and even to offer to pay the half crowns for the notifications of small-pox in that burgh, while the medical officer of Glasgow traces a case of small-pox which occurred lately in that city to infection from Leith, a place which he recommends should be shunned by Glasgow citizens. The Leith Town Council, rightly or wrongly, still hold out against compulsory notification, although urged thereto by almost all the medical practitioners in the town, by the Board of Supervision, and by other bodies. The plea that without proper hospital accommodation it would be useless is a weak one, for the present hospital arrangements are admittedly poor, and it is the fault of the Council themselves that they have not long before now provided adequate and healthy buildings for the purpose.

Edinburgh Fever Hospital.—The Edinburgh Town Council have still before them the question of the enlargement of the City Fever Hospital, and the Health Convener has brought forward a plan which will cost somewhere about £120,000, to enlarge it on its present site. To enable this to be done, part will have to be built on ground which is at present divided from the existing hospital by a densely-populated street, over which a bridge must needs be carried. Although the hospital is in the middle of the city, statistics have been prepared which show that the adjacent streets are not more subject to infectious diseases than others in remoter parts, while the mortality tables of the hospital compare favourably with those of the Belvidere, in Glasgow, although the one is old-fashioned, and all the wards massed together, while the other is built in isolated blocks on the latest plan.

Too Comfortable in the Poorhouse.—A meeting of the Kyle Union Board was held on the 28th May. The Governor's report showed that the daily average number of inmates for the quarter was 140, as compared with 126 for the corresponding period of last year. It appeared from the Visiting Officer's report that he was of opinion that the house was too comfortable, and he thought if the allowance of tobacco to the male inmates was stopped, and tea-making prohibited, it would diminish the number of inmates. The General Committee were of opinion that the large increase in the number of inmates was due to the number of labourers attracted to the district by the railway extension between Maybole and Stranraer, and to the *severity* of the past winter. The Board were unanimously of opinion that it would be a pity to deprive the inmates of their small privileges.

Glasgow Hospital for Skin Diseases. — The thirty-third annual general meeting of the subscribers to the Glasgow Hospital for Skin Diseases was held on 30th May, when Professor McCall Anderson submitted the medical report. It is stated that during the year 1,460 new cases were admitted to the hospital, making a total of 40,872 cases since 1861. While 106 of the more serious cases were received into the cutaneous wards of the Western Infirmary, making 1,734 in all since these wards became available. The donation of £500 from the Bellahouston Trust had enabled the managers to clear off the whole of the debt on the Elmbank premises. The report also referred with satisfaction to the good beginning made with workmen's subscriptions, the amount received under this head being £16 7s., and the total subscriptions for the year amounted to £260 17s. 9d.

Doctor's Action for Slander.—In Dunfermline Small Debt Court, Sheriff Gillespie decided the case brought against a cabinet maker by Dr. A. Lees Bell, both of that town. Pursuer claimed £100, restricted to £12, as damages for defender having made false and calumnious statements regarding him. Defender had offered to make a public apology for repeating a rumour, but the pursuer would not accept an apology unless defender undertook to pay a sum of £5 towards the funds of a local charity. The defender had refused to settle the case on this condition, and asked the Sheriff to assess the damages. Taking into consideration the fact that defender had offered an apology, the Sheriff fixed the damages at £3, with 14s. 3d. of expenses.

◆

Literary Notes and Gossip.

The second volume of the "Edinburgh Hospital Reports," the first volume of which met with such a favourable reception on publication last year, will appear in June, under the chief editorship of Dr. C. W. Cathcart.

⁂

Mr. Lawson Tait has in hand an autobiographical sketch of the late Dr. Chas. Clay, of Manchester, of much professional interest. Unfortunately, the material is deficient in events from 1842 to 1850, and his biographer seeks the co-operation of any members of the profession who can supply the necessary information. Mr. Tait's letter will be found in another column.

⁂

Messrs. J. Wright & Co., of Bristol, are issuing two forms of "Prescription Books." The one before us contains 150 forms, 6½ by 4 inches, perforated to facilitate detachment, on good white paper, bound together in a neat volume. The other, we are informed, contains 100 pages in duplicate, so that the prescriber obtains the prescription and copy at one writing. The price of either form is 1s. Smaller sizes of the same are also procurable.

⁂

The literature of "Hospital Sunday" has been further enriched by a four-page reprint from the *Lancet* which was placed in the seats of the various places of worship on Sunday last. This is distinctly enterprising by our contemporary, and if we can summon up sufficient courage to the task and induce the *British Medical Journal* to do the same, each of the three leading medical journals might next year send its "epistle to the churches" for the edification thereof!

⁂

The appearance of the fifth edition of the "Formulaire des Médicaments Nouveaux and des Médications Nouvelles," by M. Bocquillon-Limousin (Baillière et fils. Paris, 1894), within so short a time of its predecessor, is, we presume, evidence of this little work having "supplied a long-felt want." The additions are numerous and important, and they comprise drugs of which we have *heard* along with many others of which even the names are as yet unfamiliar to us. With the preternaturally rapid increase of therapeutical agents some such guide as this is indispensable to the practitioner, and those to whom the French language does not constitute an obstacle will welcome this handy little volume.

⁂

Published by the same well-known firm is a twin-work with the foregoing, this being the "Formulaire des Eaux Minérales de la Balnéotherapie et de l'Hydrotherapie," by Dr. de la Harpe. If the therapeutics of the natural mineral waters may safely be ignored by practitioners who minister to the wants of the working classes, it is quite otherwise with physicians who number among their *clientèle* patients of the class whose ailments, at certain periods of the year, are supposed to be amenable only to a sojourn in one or other of the famous spas of Europe. To the latter a smattering, at any rate, of the properties claimed for this or that water is indispensable, and this can be obtained from this little volume. Though the spas of France and Switzerland naturally appear the most important to a Swiss author, those of Germany also find a mention, and England is credited with one, viz., Bath.

⁂

That stupendous work ("Index Catalogue of the Surgeon-General's Office, U.S.A.") is drawing to a close, and when completed, it will remain as a monument to the patient industry and untiring zeal of Dr. John S. Billings, the librarian. Nothing but an intense love of books, together with a great familiarity with medical literature, could have successfully carried out this prodigious undertaking, an undertaking which makes all medical scholars his debtor. This volume includes 10,124 author titles, representing 6,426 volumes and 8,850 pamphlets. It also includes 9,867 subject titles of separate books and pamphlets, and 38,461 titles of articles in periodicals.

⁂

A new edition of "Aids to Examinations" has just made its appearance from the pen of Mr. David Walsh, M.B., previous editions having borne the name of Mr. Douglas Hemming, now deceased. This little volume has been entirely rewritten; it deals with medicine, materia medica, midwifery, pathology, and forensic medicine under the form of detailed answers to examination questions. It certainly contains a surprising amount of up-to-date knowledge presented in a readily available form. Mr. Walsh has brought a wide amount of reading to bear upon the subjects of which he treats. His statements are trustworthy, and the book can be cordially recommended not only to students but also to practitioners who require modern facts in small compass.

⁂

Dr. Linn's "Guide to the Health Resorts of Europe"

(Wright and Co., Bristol, 2nd Edition) has been carefully revised and brought up to date. The several descriptions, although brief, afford useful information to those in search of it on all the more important medical stations in Europe, special attention being given to the sanitation of each resort and to its hygienic condition generally. A useful addition to the volume appears in the shape of a handy reference map, folded and neatly packed in a pocket in the cover, in which the seaside health resorts are underlined in blue, and the smaller country or inland places in black, while important suggestions made by competent authorities have met with attention, and tend to increase the usefulness of this handy book.

⁂

An article on the "London Cellar Bakeries" appeared in the current number of the *New Review* written by the editor of a trade journal, *The Bakers' Times*. The general tenour of its arguments is to defend the existing state of affairs and to minimise the insanitary abuses lately disclosed by Dr. Waldo in the columns of The Medical Press and Circular a few weeks since. We regard it as unfortunate that a magazine should publish an article of this kind from the pen of an individual whose interests are so clearly involved in the defence of the master bakers. As the columns of such a magazine are closed against discussion, its readers are in this case presented with an unfair and one-sided view of an important sanitary topic. It is characteristic of the attitude of the editor in question and his friends, that the health of the unfortunate workmen is never even mentioned in their discursive speeches and articles on this "burning" question.

⁂

In the current number of the *International Journal of Microscopy and Natural Science* (Baillière, Tindall, and Cox) appears a translation of the first portion of a valuable memoir by Dr. Filandro Vicentini, of Chiete, on the bacteria found in the sputa of whooping-cough. A summary is given of previous researches on the subject, and this is followed by reports on clinical cases in which the sputa, especially prepared and stained, have been examined. The text is illustrated by an elaborately coloured plate in which the various bacterial forms are depicted at different stages of development of the bacteria and cryptogamic bodies of the mouth generally. The remaining sections of the memoir will deal in detail with myelin and fungi of the sputa, and particulars will also be given of the best methods of preparing and staining specimens, so that the contribution may be expected to form a valuable addition to the literature of the subject.

⁂

The little pamphlet ("Causes of Voice Failure," by Mrs. Emil Behnke) has the merit of being practical and of containing some truths which must appeal forcibly not only to singers but also to listeners. The authoress finds that the most frequent and most injurious mistakes leading to vocal failure are: 1. Wrong methods of breathing and of breath management; 2, loud singing and shouting; 3, neglecting to cultivate the resonators; 4, forcing, (*a*) the register, (*b*) the top notes. The evils attending these faulty methods of voice production are then pointed out both from an anatomical and from an artistic point of view; diaphragmatic breathing being especially insisted on in opposition to mere clavicular breathing; this is undoubtedly correct; but we think the advice here embodied would have been even more valuable had the authoress mentioned if from her experience she thought it applied in an equal extent to both sexes, as it is well known that nature, or we may perhaps more correctly say, the art of dress, causes women to breathe in a far more "clavicular manner than men.

⁂

We generally look for some evidence of original research in a monograph on any given subject, this being really the only *raison d'être* of such publications, yet in his monograph on sciatica, Dr. A. Symons Eccles expressly disclaims any novelty, either in the views expressed in regard to the nature of sciatica or in the methods advocated for its relief! In this the author does himself an injustice, for if, strictly speaking, no individual fact owes its elucidation to his researches, he is certainly entitled to the credit of having co-ordinated existing knowledge on the subject, and of making it relevant to the issue—which is the relief of a very distressing and disabling affection. As sciatica is tolerably common in such a climate as ours we can confidently recommend this monograph to the notice of practitioners who have such cases, for they will not only find assistance in arriving at an exact diagnosis—not so easy a matter as might be supposed—but will materially extend the scope and usefulness of remedial intervention.

⁂

New Books and New Editions.—The following have been received for review since the publication of our last monthly list:—A Manual of Diseases of the Ear, by George P. Field, M.R.C.S. (Fifth Edition). Diseases of the Nose and Throat, by F. De Haviland Hall, M.D., F.R.C.P. Lond. The Physician's Wife, by Ellen M. Fairbaugh. An International System of Electro-Therapeutics, by H. R. Bigelow, M.D. Biological Lectures and Addresses, by A. Milnes Marshall, M.D., F.R.S. Die Bedentung der Hypnotischen Suggestin, von Dr. Med. J. Grossmann. Analyses of Twelve Thousand Prescriptions, compiled by W. Martindale, F.C.S. Micro-organisms in Water, their Significance, &c., by Percy Frankland, Ph.D., F.R.S. Clinical Medicine, a Manual for Students and Junior Practitioners, by J. S. Bury, M.D., F.R.C.P. Materia Medica, Pharmacology, and Therapeutics, by C. D. F. Phillips, M.D., F.R.S.Ed. (2nd Edition). Hydatid Disease, by the late John D. Thomas, M.D., F.R.C.S., edited by A. A. Lendon, M.D.Lond. Supplement to the Calendar Royal University of Ireland, 1894. Army Medical Report for 1892, vol. xxxiv. Nature's Hygiene, a Systematic Manual of Natural Hygiene, by C. T. Kingzett, F.I.C., F.C.S. Brain, part lxv. Manual of Hygiene, by J. W. Wallis. The Mother's Help and Guide, by P. M. Braidwood, M.D., F.R.C.S. Spinal Caries, by Noble Smith, F.R.C.S.Ed.

THE PENAL CLAUSES OF THE MEDICAL ACT.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am not quite certain that the British Medical Association possesses any valid claim to speak in the name of the profession; and I am much less certain whether the Parliamentary Bills Committee of the Association has any warrant to operate in the name of the Association. But to everyone who has an intimate acquaintance with medical legislation, and has followed the practical working of medical laws in late years it must seem very clear that if the proposed amendment of the penal clauses of the Medical Act presented for acceptance to the General Medical Council last week by the Committee, represents the best that the combined wisdom of the profession is able in this direction to produce, the prospects of protection of the public or profession against the grosser forms of quackery must be remote indeed. Nothing could be much more fatuous than the enumeration of titles in clause 2. If it is possible to drive a coach and horses through the present penal section, it would be possible to drive six abreast through this precious amendment. It will need the most stupid of quacks and the most arbitrary and severe of magistrates to come into collision before any conviction for a flagrant offence is obtained. Why, for instance, specifically mention doctor of medicine as a title forbidden to the unqualified? No quack wants to call himself doctor of medicine; he merely needs to add the prefix "Dr." to his name. This is the title by which the public know every medical practitioner. If challenged, he may be a doctor of philosophy, of music, or of dentistry. For a few pounds he can always possess himself of an American diploma of several such doctorates, and that no magistrate will convict is certain from the experience of attempts to enforce present laws. Dr. ———'s establishment for diseases of the eyes, or ears, or teeth is enough without use of the forbidden designations, aurist, oculist, &c.—these simply show the quack what to refrain from in order to keep clear of the law. An honest unqualified practitioner —in the existence of which the law at least believes—will assume no equivocal title; the fraudulent quack can be effectually dealt with only by a law which shall forbid in general terms the assumption of *any* medical title by an unqualified person practising for gain.

I am, Sir, yours, &c.,
S.

May 30th, 1894.

◆

THE "ANTI-MEASLY" TREATMENT OF MEASLES.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I know nothing whatever of "C. R. Illingworth, M.D.," or his treatment.

I never heard of "The Anti-Measly Treatment of Measles," and desire to know nothing about it. I never made any statement of any kind whatever upon any subject whatever to the "Year-book of Treatment for 1890," or any other year. I know nothing whatever as to what is found useful or useless in the London Fever Hospital.

I have never referred enthusiastically and confidently to the curative treatment of syphilis, and I have never accused anyone of being "no clinician," or of "rashly vaunting a remedy."

In spite of these facts, a letter signed by "C. R. Illingworth, M.D." appears in your issue of May 30th, which contains a grave libel upon me, and accuses me of lying in regard to these matters. I have, of course, placed the matter in the hands of my solicitors.

I am, Sir, yours, &c.,
Leslie Phillips.

⁂ [Dr. Illingworth, having evidently made a mistake as to authorship, will doubtless make the *amende* to which Dr. Leslie Phillips is undoubtedly entitled.—Ed.]

◆

BINIODIDE OF MERCURY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Lately having prescribed for secondary symptoms, Liq. Hyd. Perch., with Potass. Iodid., the mixture being flavoured with Syr. Currant, the patient sent the mixture back to the druggist in alarm at some white matter which deposited in the bottle. I put the substance under 1-5th power, and found a beautiful and branching micelium.

My powerful germicide mixture if continued long enough will no doubt cure the secondaries, but I am not converted to any definite belief that such result will be due to killing "germs." The expression is too vague for positive belief or dogma; the germ-statement is, however, a legitimate temporary hypothesis.

But it is interesting to note that a micelium grew in the germicide mixture with great vigour. Thus, one may fairly doubt the power of the biniodide to destroy so many enemies!

I have used, of late, the biniodid. of mercury in sodii iodid. solution in ringworm, and I think the results have been very satisfactory. Formerly, I used sulphurous acid, glycerin. acid carbol, or ung. hyd. nit., &c., and my cases did well; but, as far as I can judge at present, and it is very difficult to estimate the value of remedies, the biniodid. in sodii iod. solution is more rapid and more sure than the other applications.

The ubiquity and polymorphism of "germs" are, I fear, too cunning and varied to be wiped out by any one remedy —as my micelium, *to wit*.

I am, Sir, yours, &c.,
Receptive.

Plymouth, June 2nd, 1894.

◆

COUNTER-PRESCRIBING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Although your correspondents have hitherto appeared unanimous in condemning the revolutionary proposal of Sir Benjamin Richardson, it is curious to note that Dr. Norman Kerr now occupies the position of a waverer. "Although not convinced," he nevertheless thinks "nothing but good can come from a thorough discussion of Dr. Richardson's suggestions." One of two things, therefore, must be evident, that is to say, either Sir Benjamin Richardson is gifted with remarkable persuasive powers, or else Dr. Norman Kerr is easily open to conviction. It might appear at first sight that it a proposal of this kind were at all feasible steps would have been taken a generation ago, before diagnosis and general medical research had achieved their present standard, to introduce a clause in the Medical Acts exempting chemists to some degree from the provisions of these Acts, but so far from any relaxation having taken place in their favour in those rude and rough times, chemists themselves have since been placed by a Pharmaceutical Act under more or less restraint. I merely observe this because, no doubt, in bygone days, when the line of demarcation between a chemist and medical man was not nearly so pronounced as it now is, there might have been some conceivable recognition ot chemists as prescribers of medicine; but seeing how they have been completely isolated one from the other by distinct Acts of Parliament the contrast between the past and present appears to me to bring out in bold relief the almost miraculous conception of Sir Benjamin's proposal. Dr. Norman Kerr, in his letter of the 16th inst., very properly said, "There is a wide difference between tacitly permitting and legalising," and no doubt a good deal is done nowadays by chemists which is not strictly legal, but which is winked at, and this is one thing: but Sir Benjamin Richardson's proposal, which practically yields the whole range of medical diagnosis in the first instance into the hands of chemists (ground which has been ably covered by your other correspondents) is assuredly quite another.

I am, Sir, yours, &c.,
Clement H. Sers.

Queen's Road, Peckham, May 31st, 1893.

THE VIVISECTION CONTROVERSY—CORN OR CHAFF?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—No one regrets more than I do the bitter feeling which now exists between certain self-appointed champions of the medical profession and a large section of the public, which has evidently lost confidence in some of our principal hospitals. Whether my letter will be found as "oil upon the waters" or not, I cannot predict; but, as I have not hitherto had anything to do with the hospital controversy, perhaps I may be allowed to say a word to clear the atmosphere. Your essayist is in some confusion about the "London Anti-Vivisection Society," as the bishop who was expected to preside was not present at their annual meeting, and consequently could not have made the remark referred to in your article.

Besides, it must be difficult to decide what a bishop does or does not believe. Some clergymen are so largely endowed with theological faith that there seems no sufficient reason for disputing their sincerity in other matters.

But, on the other hand, are we not called on to believe a little too much when some six score of vivisecting enthusiasts are made to represent the views of 40,000 medical practitioners, and are allowed to talk in the medical journals in the name of the profession? As one of its humblest members, I protest against these men (whether natives or foreigners) being considered as our representatives. That knowledge is often gained by experimental research goes without saying. But what of its tendency to mislead, and of the proved danger of following the dictates of these theorists? Is Dr. Koch's cure for consumption and lupus so very dead that the manner in which many leaders in the profession identified themselves with his secret remedy has been quite forgotten? Surely so-called "scientific experimentation" has a good deal to answer for. With regard to the position assumed in the latter part of your article, I think it is at once too hopeful and too modest. I do not believe that science can ever give us a general law applicable to *all* cases of disease, and I admit that we have to contend with much difficulty and uncertainty in the acquisition of knowledge. But, when it is once gained, it is no longer uncertain, and it ought to be simple in its application. When you speak of "conflicting interpretations," you describe only too accurately the disputes of experimenters, who seem never to arrive at finality, even after sacrificing *hecatombs* of victims!

Where I think you are too modest is in doubting the existence of laws of general applicability to large classes of cases, and thoroughly reliable, as being based on repeated observation.

All the laws of hygiene are of this character, and if medicine is ever based upon any other foundation, it can only come of that pride which "goes before destruction" and forgets the true limits of the physician's art. I do not care to bring the personal element forward in this discussion, and have no ambition to have my name "rescued from obscurity" by publication. I therefore have the honour to subscribe myself,

Your obedient servant,
E. H.

◆

NOTIFICATION AND ITS RESULTS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Mr. Wynter Blyth in his latest Health Report gives ground for believing that scarlatina, which has hitherto run a distinctly seasonal course (being most prevalent in the autumn and least in the spring). will, with a few intermissions, go on, not diminishing, but increasing. This certainly looks like an admission that notification has done but little in the past towards checking this disease, and is likely to do but little in the future. Mr. Biddle gives me the following figures deduced from the report above mentioned:—In London, with a population of 4,300,000, there were in 1893 no less than 56,425 notifications of infectious fevers, or 1 in 76 of the population. Of these 18,674 were treated in the Asylums Boards Hospitals, *i.e.*, 33·1 per cent., or 1 in 230 of the population. What the number of unnotified infectious cases was it is impossible to say. While we must remember that no account is taken of measles, rotheln, chicken-pox, diarrhœa, &c.

The population of London in 1894 being estimated at 4,349,000 there were in the infectious hospitals on May 26th last—

236 persons with small-pox, or 1 in 18,428
2,271 „ „ scarlatina, or 1 in 1,915
324 „ „ diphtheria, or 1 in 13,423

The number of enteric fever patients does not appear, but these three diseases alone account for 2,831 that were isolated in fever wards, and that is equal to 1 in 1,536 of the population. It is well known that the Asylums Board are already finding difficulty in providing for all cases of diphtheria, and it has been officially declared that, supposing things go on in their usual course, the hospital accommodation is within measurable distance of being exhausted. Such a state of things cannot but call for immediate consideration.

I am, Sir, yours, &c.,
F. P. Atkinson.

Surbiton.

Medical News.

The West London Hospital.

The Annual Subscription Dance in aid of the Extension Fund of the West London Hospital will take place at the Queen's Hall, Langham Place, W., on Tuesday, June 12th, under the immediate patronage of H.R.H. Princess Louise (Duchess of Fife), and H.R.H. Princess Mary Adelaide (Duchess of Teck). The list of patronesses and all other information in respect to the tickets may be obtained from the Honorary Secretaries, Mr. Percy Dunn, 54 Wimpole Street, and Mr. Leonard A. Bidwell, 59 Wimpole Street, London, W.

Society for Relief of Widows and Orphans of Medical Men.

At the annual general meeting of this Society, held a few days since, under the chairmanship of the President, Sir James Paget, the report, read by the Secretary, showed that 13 new members had been elected in 1893, 15 had died, and 2 resigned, leaving 308 on the books. Fresh applications for grants had been received from 2 widows and 1 orphan; 6 widows had died and 4 children had become ineligible for further grants. A sum of £2,880 10s. had been distributed among the widows and orphans receiving assistance. At the end of 1893 there were 54 widows and 9 orphans on the funds of the Society. The expenses of the year had been £250. The receipts available for the payment of grants and expenses had been £3,247. A legacy of £791 had been paid, and the funded property increased by the purchase of £843 10s. stock. A vote of thanks to the editors of the medical journals for their kindness in making known the objects of the Society was passed. The following gentlemen were elected to fill the vacancies in the officers of the Society: Mr. Merriman, a Vice-President; Dr. Church, a Treasurer; and Dr. Braxton Hicks, Dr. Russell Reynolds, Dr. Morison, Mr. Rouse, Mr. Langton, Dr. Oswald, and Dr. Wharton Hood, Directors. A vote of thanks to Sir James Paget for his kindness in presiding at the meeting was carried unanimously.

Volunteer Medical Staff Corps.

The annual dinner of the officers of the London companies of the Volunteer Medical Staff Corps was held last week at the Café Royal, Regent Street. The chair was taken by Surgeon-General Sir Guyer Hunter, and amongst those present were Surgeon-General Sir Thomas Crawford, the Master of the Society of Apothecaries, Brigade Surgeon-Lieut.-Colonels Evatt and Clark, Surgeon-Major Hayes, and others. Surgeon Lieut.-Col. Norton (Commandant) proposed the toast of "The Army, Navy, and Reserve Force." In submitting "The Volunteer Medical Staff Corps," Surgeon-General Sir Thomas Crawford congratulated the corps that they were the only body of Volunteers that had from the first been intended for general service. Although they could not be sent out of the country without specially offering themselves for the purpose, nobody had any doubt that the corps would volunteer for such service the moment their assistance was required. Surgeon Lieut.-Colonel Norton, in reply, spoke of the services rendered by Sir Thomas Crawford (then Director-General of the Army Medical Department) in connection with the formation of the corps. Other toasts followed. The annual dinner has always been a great feature of the regimental year, and on this occasion proved a more than ever brilliant and successful affair.

The West London Medico-Chirurgical Society.

On Wednesday, May 30th, the members of the West London Medico-Chirurgical Society held their annual dinner at the Criterion. Including visitors about eighty gentlemen assembled, Dr. Donald W. C. Hood, the President of the Society, being in the chair. After the usual loyal toasts, proposed in very felicitous terms by the president, the toast of the evening, that of "The West London Medico-Chirurgical Society," was given by Sir W. Broadbent, the Cavendish Lecturer, who, after alluding to the rapid growth of the Society during the twelve years of its existence, dwelt on the great utility of such societies as antidotes to the natural laziness of the human species. The health of the visitors was then proposed in a humorous speech by Mr. Keetley, and responded to by Dr. Eastes, President of the Harveian Society; the last toast being that of the "Officers of the Society," proposed by Mr. Bowreman Jessett, and answered by Dr. Clemow.

St. Thomas's Hospital.

The following gentlemen have been selected as House Officers from Tuesday, 5th June, 1894:—

Resident House Physicians: R. E. Nix, B.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S.; A. M. Collcut, M.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S. **Non-Resident House Physicians**: F. Pershouse, L.R.C.P., M.R.C.S. (extension); C. W. Windsor, M.A., M.B., B.C., Cantab. (extension). **House Surgeons**: S. W. F. Richardson, B.Sc.Lond., L.R.C.P., M.R.C.S; E. M. Hainworth, B.Sc.Lond., L.R.C.P., M.R.C.S.: A. R. O. Milton, L.R.C.P., M.R.C.S.; G. W. Thompson, B.A., M.B., B.C.Cantab, L.R.C.P., M.R.C.S. **Assistant House Surgeons**: L. J. Miskin, L.R.C.P., M.R.C.S.; A. W. Cuff, B.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S.; **Obstretric House Physicians**: (Senior) C. S. Jaffé, M.B., B.S.Lond., L.R.C.P., M.R.C.S.; (Junior) P. C. Fenwick, L.R.C.P., M.R.C.S. **Ophthalmic House Surgeons**: J. H. Fisher, F.R.C.S., L.R.C.P.; J. F. Rudall, M.B., B.S.Melb., M.R.C.S. (both reappointed). **Clinical Assistants in the Special Departments for Diseases of the—Throat**: F. E. Appleyard, B.A.Cantab., L.R.C.P., M.R.C.S.; A. F. W. King, L.R.C.P., M.R.C.S. **Skin**: T. G. Nicholson, B.Sc.Lond., L.R.C.P., M.R.C.S.; A. S. F. Grunbaum, B.A., Cantab., L.R.C.P., M.R.C.S. **Ear**: C. W. Cooke, M.D. Lond., L.R.C.P., M.R.C.S. (extension); R. Fox Symons, L.R.C.P., M.R.C.S.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE LATE DR. CHARLES CLAY, OF MANCHESTER.

To the Editor of The Medical Press and Circular.

Sir,—The representatives of this distinguished surgeon have placed at my disposal a mass of material for the preparation of a suitable memorial of him, including an autobiographical sketch of much interest.

Unfortunately the material is deficient in that period of his life which is of greatest interest, between 1842 and 1850. A still greater misfortune is that the great age to which Dr. Clay lived has left few who can tell much about him at that time. My own efforts by private inquiry have failed so far, and I am therefore compelled to trespass on your courtesy for permission to ask through your widely-read columns that any who may be in possession of documents or recollections of Charles Clay would be good enough to lend them to me for the purpose specified.

I am, Sir, yours, &c.,
Lawson Tait.

7 The Crescent, Birmingham.

Fable.—Our correspondent will find on reference to another column, the obvious reason why his contribution is held over.

THE CAMBRIDGE EXAMINATION IN STATE MEDICINE.

We are asked by the Registrar to state that the names of all candidates for examination in State Medicine, together with the necessary certificates, must be sent to him on or before Tuesday, Sept. 18th. The examination will begin on October 2nd.

LADY DOCTORS FOR INDIAN HOSPITALS.

In the advertising columns of our present issue will be found an announcement which at first sight appears a little startling. It runs thus: "Wanted, a lady doctor for the post of *First Physician* to the Kama Hospital," &c. The lady selected will come under the ordinary rules for "leave, pension," &c. The ladies are to be congratulated that the ball is being kept rolling for their especial benefit.

Meetings of Societies, Lectures, &c.

Wednesday, June 6th.

Obstetrical Society of London.—At 8 p.m. Specimens will be shown by Dr. Crawford, Dr. Blacker, Dr. Lewers, Dr. Horrocks, Dr. Cullingworth, and Mr. J. Bland Sutton. Dr. Remfry: Ligature and Division of the Upper Part of both Broad Ligaments, and the Result as compared with that following Removal of the Uterine Appendages.—Dr. Braithwaite: A case of Adenoma of the Portio Vaginalis Uteri forming a Depressed Sore or Ulcer.

London Post-Graduate Course.—Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Lupus Vulgaris.

Metropolitan Hospital (Kingsland Road, N.E.).—At 5 p.m., Mr. Walsham: Diseases of the Nose and Naso-pharynx. (Post-Graduate Lecture.)

Royal College of Surgeons, England.—At 5 p.m., Prof. Raymond Johnson: Tumours of the Breast.

West London Hospital (Hammersmith).—At 5 p.m., Mr. Keetley: Orthopædic and other Surgical Cases. (Post-Graduate Course).

Thursday, June 7th.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street.—At 3.30 p.m., Mr. Bernard Pitts: Treatment of certain Congenital Deformities in Children.—National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Charlton Bastian: Aphasia and other Speech Defects.—Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. Watson Cheyne: Cases in the Wards.

Friday, June 8th.

London Hospital Medical College.—At 4 p.m., Mr. Jonathan Hutchinson: On the Eruptions which Occur after Vaccination.

Royal College of Surgeons, England.—At 5 p.m., Prof. Raymond Johnson: Tumours of the Breast.

Royal Institution.—At 9 p.m., Mr. C. Vernon Boys: The Newtonian Constant of Gravitation.

Saturday, June 9th.

London Post-Graduate Course.—Bethlem Hospital.—At 11 a.m., Dr. Percy Smith: Alcoholic Insanity.

Monday, June 11th.

Royal College of Surgeons, England.—At 5 p.m., Prof. Thorburn: The Surgery of the Spinal Cord and its Appendages.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Syphilides.

Vacancies.

Carlow District Lunatic Asylum.—Assistant Medical Officer. Salary £100 per annum, and emoluments valued at £100 per annum. Election June 8th. (See advert.).

Coventry and Warwickshire Hospital.—House Surgeon and Assistant House Surgeon. House Surgeon's salary £100 per annum, and Assistant £15 per annum. Applications and testimonials to the Secretary on or before June 18th.

Devizes Union.—Medical Officer. Salary £25 per annum, with the usual extra fees. Applications and testimonials to the Clerk on or before June 12th.

Earlswood Asylum for Idiots, Redhill, Surrey.—Medical Superintendent (married preferred). Salary £500 per annum, with furnished residence in the building, together with coals and gas. Applications and testimonials to the Board of Management, 36 King William Street, London Bridge, E.C., on or before June 12th.

Leicester Infirmary.—Assistant House Surgeon. Salary £80 per annum, with board, apartments, and washing. Applications and testimonials to the Secretary, 24 Friar Lane, Leicester, on or before June 11th.

Parish of St. Pancras.—Medical Superintendent. Salary £400 per annum, with house, &c. Applications and testimonials to Clerk to the Guardians on or before June 12th.

Royal Berks Hospital.—Assistant House Surgeon. No salary, but board and lodging will be provided. Applications and testimonials to the Secretary on or before June 12th.

Sunderland Borough Lunatic Asylum.—Medical Superintendent. Salary £350 per annum, with furnished house, &c. Applications and testimonials to Clerk to the Visiting Committee on or before June 30th.

University of Edinburgh.—Chemical Assistant. Salary £180 per annum. Applications and testimonials to the Secretary on or before July 1st.

Wexford Union.—Broadway Dispensary.—Medical Officer. Salary £125 per annum, and £15 per annum as Medical Officer of Health. Election June 15th.

Appointments

Hale, E. S., L.R.C.P., L.R.C.S., L.M.Edin., Medical Officer for the Fourth Sanitary District of the Bedminster Union.

Hancock, R., M.R.C.S., Government Medical Officer at Childers, Queensland.

Hartnell, E. B., Junior House Surgeon to Chesterfield Hospital.

Hutton, H. R., M.A., M.B.Cantab., Physician to the Manchester Hospital for Consumption and Diseases of the Throat.

McGowan, R., L.F.P.S.Glasg., Government Medical Officer for the District of Silverton, New South Wales.

Moore, T. C., M.D.Dub., Ch.B., Medical Officer of H.M. Prison at Napier, New Zealand.

Bake, A. T., M.B.Lond., F.R.C.S., Registrar and Pathologist to the East London Hospital for Children, Shadwell, E.

Reid, J. A., M.D., Ch.M.Aberd., Health Officer for the Borough of Sale, Victoria, Australia.

Rudd, A., L.R.C.P.Lond., M.R.C.S., Medical Officer for the First Sanitary District of the Parish of St. Giles, Camberwell.

Santi, P. R. W., L.R.C.P.Lond., F.R.C.S., Surgical Registrar to the Westminster Hospital, S.W.

Saunders, W. S., M.D., M.R.C.S., Medical Officer of Health and Public Analyst for the City of London.

Senior, E. W., M.R.C.S., L.R.C.P., House Physician to the East London Hospital for Children, Shadwell, E.

Syme, W. S., M.B., C.M.Edin., Medical Officer for the Third Sanitary District of the St. Neots Union.

Troutbeck, H., M.A., M.B., B.C.Cantab., House Surgeon to the East London Hospital for Children, Shadwell, E.

White, T. G., L.K.Q.C.P., L.M., L.R.C.S.Irel., Surgeon to the Geraldton Hospital, Queensland.

Wilson, J. G., M.A., M.B., Dispensary Surgeon to the Tradeston Dispensary of the Victoria Infirmary, Glasgow.

Births.

Baker.—May 28th, at Norfolk Terrace, London, the wife of William H. Baker, M.R.C.S., L.R.C.P., of a daughter.

Barrow.—May 31st, at Uffculme, Devon, the wife of Valentine E. Barrow, L.R.C.P., of a son.

Musson.—May 31st, at 15 King Street, Clitheroe, the wife of Alfred W. Musson, M.B.Cantab., of a son.

Sansom.—June 2nd, at 8 Wilton Street, Grosvenor Place, London, the wife of Dr. C. L. Sansom, F.R.C.S., of a son.

Scott.—May 31st, at Elmsleigh, Plymstock, the wife of S. Noy Scott, L.R.C.P., M.R.C.S., D.P.H., of a son.

Warriner.—May 29th, at De Crespigny Lodge, Denmark Hill, the wife of Dr. J. Warriner, of a son.

Marriages.

Ealand-Coad.—June 2nd, at Holy Trinity Church, Upper Tooting, Hugh Fawsit Ealand, L.R.C.S., L.R.C.P., L.S.A.Lond., of Puckeridge, Herts, to Edith Agnes Cochrane, second daughter of Thomas Coad, R.E.E., of the Horse Guards, Whitehall.

Ward—Chadwick.—June 2nd, at St. George's, Hanover Square, Howard Percy Ward, M.B.Lond., M.R.C.S., to Amy, daughter of the late John Chadwick, J.P., of Buile Hill, Manchester.

Deaths.

Brown.—May 27th, at Westbourne, Dumfries, Samuel Brown, M.D., L.R.C.S.Ed., late of Bradford, Yorks, aged 74.

Hunt.—May 27th, at St. George's Square, S.W., John Hunt, M.R.C.S., aged 71.

Jackson.—June 2nd, at the Rectory, Belturbet, Dr. Charles Jackson, of Ballyhaise, in his 49th year.

Kipling.—May 29th, at Romaldkirk, William Kipling, M.R.C.S., L.S.A., L.R.C.P.Lond., aged 47.

Reece.—June 3rd, at his residence, Walton-on-Thames, Richard Reece, M.R.C.S., L.S.A., aged 90.

Saunderson.—June 1st, at Edenderry, Robert Saunderson, M.D.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

THE FACTORS OF INSANITIES.

By J. HUGHLINGS JACKSON, M.D., F.R.C.P.Lond., F.R.S.,

Physician to the Hospital for Epilepsy and Paralysis; Consulting Physician to the London Hospital.

I HAVE often urged that for the scientific study of maladies of the Nervous System we should investigate them as Dissolutions (reversals of Evolution) of this or that part of the nervous system; we must also take into account the undamaged remainder—the evolution still going on in what is left intact of a nervous system mutilated by disease. The supposition is that the principle indicated will ultimately be found to apply to all nervous maladies—from those produced by lesions at the periphery of the nervous system, to those produced by lesions of the highest cerebral centres—from, for example, those produced by lesions of nerve trunks to ocular muscles, to cases of insanity. I have never put forward the opinion that nervous maladies should be classified on the principle of dissolution for clinical purposes, but, on the contrary, have urged that for those purposes we should continue our empirical arrangements of cases by types. In particular I have urged the necessity of arrangements by type of cases of Insanity for clinical purposes, as well as the study of them, as they exemplify Dissolution of the highest cerebral centres. It would be as absurd to attempt to arrange patients in an Asylum on the principle of Dissolution as it would be to arrange plants in a kitchen garden on the "natural system" of botanists.

In every insanity there is morbid affection of more or less of the highest cerebral centres or, synonymously, of the highest level of evolution of the cerebral subsystem, or, again synonymously, of the anatomical substrata, or physical basis, of consciousness. There may be discoverable disease destructive of nervous elements, or there may be loss of function from some undiscovered pathological process inferred from symptoms. In every insanity more or less of the highest cerebral centres is out of function, temporarily or permanently, from some pathological process; for my present limited purpose it matters little what that process may be. It only matters as the pathological processes produce loss of function, that is Dissolution, of more or less of the highest centres, *at different rates* (Factor 3).

I do not use the term "function" in the sense often given to it in clinical accounts of nervous maladies, as, for example, when it is said of a patient that his "case is entirely functional." I do not believe that there is such a thing as loss or defect of function of any nervous elements without a proportionate material alteration of their structure and nutrition. Of course the separation into structure, nutrition and function of the nervous system is artificial; it is merely a convenient device, just as the separation into the surface, weight and mass of a body is.

I think a better term for my present purpose than "loss of function" would be "negative lesion"; the latter term would include not only destruction of nervous elements, but also all other conditions of nervous elements from which they function no longer, for example cases where, as after an epileptic fit, certain cells and fibres, or the endings of fibres, are, for a time, of no use. If a man be so soundly asleep that he cannot be awakened, there is for the time being no help to be had from him any more than there would be if he were dead. There is a difference between destruction of nervous elements symbolised by the dead man and the temporary condition of them after an epileptic fit symbolised by the man deeply asleep, but *for the time being*, during the existence of the insanity, the cases are alike in that more or less of the highest cerebral centres is functionally absent, although in the former they are structurally absent too. Recovery (re-evolution) may occur in the latter, but does not occur in the former.

Whilst studying insanities as dissolutions we consider them so far as we can as they are *departures from* mentation concomitant with normal states of the highest cerebral centres, and not as we do for clinical purposes as they *approach* certain clinical types, melancholia, general paralysis, &c. Hence we take heed of delirium in non-nervous maladies, in pneumonia for one example, of cases of poisoning by belladonna and cannabis indica and of degrees of drunkenness from alcohol, as well as of cases of insanity ordinarily so-called (*a*).

Enough attention is not given in certain cases to degrees of insanity. Whilst epileptic (post-epileptic I think) mania is thought of as an insanity, coma after a severe epileptic fit is not regarded as an insanity. Yet post-epileptic coma is acute temporary dementia, and is psychically a greater degree of the negative mental element which co-exists with a super-position element in post-epileptic mania. There are many degrees of post-epileptic states from slightest confusion of mind to deepest coma; in a scientific regard all these degrees of insanity should be taken into account (*b*).

Dreaming has long been likened to insanity. I suggest several degrees of the normal dissolution of

---

(*a*) There are in a scientific regard many degrees of insanity caused by alcohol, from that slight degree in which a man "begins to think too curiously," to deep coma (acute temporary dementia). The taking such cases as being in a scientific regard insanities, they not being what would ordinarily, or I may say clinically, be called insanities, induces "mental diplopia." Although it is said that the term insanity is used in scientific exposition for the state of a person who has taken a very small quantity of alcohol and yet a little too much for him, only to signify a departure, a very slight one, from his normal mental state, there inevitably arises also the ordinary connotation of the term, and the notion that the case of a man slightly drunk is averred to be one suitable for a lunatic asylum; thus there is mental confusion. I can only repeat that in a scientific study of insanities we have to take into account, so far as is practicable, all degrees of departure, however produced, from normal mental states, from the slightest to the most extreme, regardless whether or not they are clinically insanities, insanities ordinarily so-called. Some very slight degrees of insanity, such as those after slight and transient epileptic fits, may be looked on as being re-evolutions: a patient as he is coming round from a slight epileptic fit may ask "Where am I?" "What day is it?" and the like; he is endeavouring to re-orient himself. But his need of such re-evolution implies slight dissolution. (I know of but a single study of re-evolution, a very valuable one by Professor Pick, of Prague.)

(*b*) In the Bowman Lecture, delivered November 13th, 1885 ("Trans. Ophth. Soc." vol. 6), I said "Deep post-epileptic coma is psychically dementia, but is, on the physical side nothing else than some universal, almost total, paralysis—paralysis not only of animal, but of organic parts also, proportionate to the degree of the prior epileptic discharge upon them. This contention of mine is, however, denied: let us say what cannot be denied, that the patient is nearly dead. I daresay my calling the psychical side of the condition insanity (dementia or amentia) will be objected to. Let us say that the patient is, or is nearly, mentally dead; this cannot be objected to."

sleep. (1) Sleepiness, (2) Sleep with dreaming, (3) Sleep with actions (somnambulism), and (4) Deep, so-called dreamless, slumber. At least 2, 3 and 4 ought to be considered as different depths of dissolution of the highest cerebral centres, with, in 2 and 3, and possibly in 4, lower ranges of evolution remaining in those centres.

There are four Factors (a) in Insanities. (1) There are different Depths of Dissolution of the highest cerebral centres. (2) There are different Persons who have undergone that Dissolution. (3) There are different Rates with which the Dissolution is effected. (4) There is the Influence of different Local Bodily States and of different External Circumstances on the persons who have undergone that Dissolution.

Although I speak of Dissolution of the highest cerebral centres as if it were uniform—as if all the divisions of these centres were "evenly" affected—it is clear enough that there are local Dissolutions of those centres. That there are different *kinds* as well as different *degrees* of insanity is evident—melancholia and general paralysis for two examples. Different regions of the highest cerebral centres undergo dissolution in different *kinds* of insanity. I shall nevertheless in this brief sketch (except incidentally for purposes of illustration) ignore *local* dissolutions of the highest cerebral centres and speak of different degrees of insanity as if the Dissolutions of those centres producing them were uniform. If we did consider local dissolutions of the highest cerebral centres we should have to say that there are five factors in insanities (b).

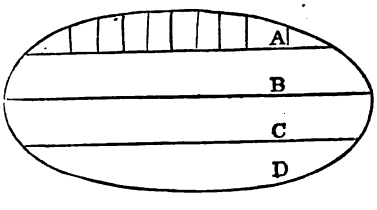
It is obvious that when studying insanities as Dissolutions—as reversals of evolution—of the highest cerebral centres we are making, by help of what may figuratively be called the experiments of disease, a study in psychology as well as one in the anatomy and physiology of a certain part (highest cerebral centres) of the nervous system. For, as I have said and I shall speak at more length on the matter later, we have in these cases to take into account not only the depths of dissolution of these centres, but also the evolution going on in the undamaged remainder of them—the mentation remaining possible when these centres have been mutilated in different degrees.

(1.) FIRST FACTOR IN INSANITIES. DIFFERENT DEPTHS OF DISSOLUTION.

No centres are in layers, but for simplicity of illustrations I shall imagine that the highest cerebral centres are in four layers, A.B.C.D. (c) In accord with this I make, still arbitrarily of course, four depths of Dissolution of these centres, and, correspondingly, four degrees of insanity.

(A) *First Depth. First degree of Insanity.*

In this depth the first, we may say topmost, layer of the highest cerebral centres is rendered functionless by some pathological process. The situation may be represented thus:—



I am obliged to stay here to consider a matter to which I attach extreme importance. I submit that, with obvious exceptions, the symptomatology of nervous maladies in which there are negative lesions is made up of two opposite elements, one negative, alone produced by disease, and one positive, or super-positive, the outcome of activities of healthy nervous arrangements. The simplest illustration of this dictum is given by the symptomatology of paralyses of ocular muscles from disease of the motor nerve trunks supplying them. In this paper I illustrate the dictum by the first depth of dissolution of the highest cerebral centres, first degree of insanity.

Whilst noting that in this, the first, degree of insanity, the layer A. is out of function, possibly permanently, we have to keep vividly in mind that the three other layers are intact. The only thing *disease*, in the proper sense of pathological process or result of one, has done, is to render functionless or to destroy the layer A., and we have necessarily to take into account the intactness, the functionability, of the layers, B.C. and D. I now try to show the importance of this.

In every insanity, (a) with one obvious exception, (complete dementia), there is a double symptomatic condition, a condition of two opposite mental elements, one negative and one positive (or super-positive). (b) Repeating what has just been said, there is in every insanity (1) negatively, defect of consciousness (loss of some (c) consciousness) and there is (2) the consciousness remaining. In the first depth of Dissolution the physical condition corresponding to the defect of, loss of some, consciousness is the abrogation of A; the physical condition corresponding to the consciousness remaining is the intactness of B.C. and D. In other words disease only causes the physical condition corresponding to the negative mental element, defect of consciousness; the positive symptoms signify, or rather they sample, the consciousness remaining, and are the outcome of activities of the layers B.C. and D. which are perfectly healthy. (d)

(a) I have several times stated what I suppose to be the factors of insanities; for the first time, I believe, in The Medical Press and Circular, Dec. 9th, 1874. when I wrote, "The varieties of insanity would be explained (1) by the depths of the reduction or dissolution; (2) by the rapidity of the reduction; (3) by the kind of brain in which the reduction occurs; and (4) by the influence of external circumstances and internal bodily states on the patient who is reduced."

(b) We rarely, if ever, meet with a dissolution from disease which is the exact reversal of evolution. Probably healthy senescence is the dissolution most nearly the exact reversal of evolution. In local dissolutions of the highest cerebral centres there plainly cannot be the exact antithesis of evolution. To take another example from the lowest level of evolution of the central nervous system. Wasting of cells of anterior horns (as in progressive muscular atrophy) being a morbid affection of motor elements only, cannot be the antithesis of evolution which is sensori-motor. Evolution may be rudely symbolised as raising an expression to a higher power (called involution in Algebra), and dissolution as reducing an expression to a lower power (called evolution in Algebra). But the quasi-random doings of disease must mostly, if not always, be symbolised as taking out some terms of an expression, and not as a reduction of the whole of it to a lower power.

(c) Of course I am not speaking of what are morphologically called layers of cells of the cortex, but of imaginary anatomico-physiological layers.

(a) As I have several times pointed out the late Dr. Monro first stated the doctrine that the mental condition in cases of insanity, is a double one—one of two opposite elements, negative and positive. Dr. Anstie and Dr. Thompson Dickson formulated the principle of "loss of control."

(b) Mind, Mentation and Consciousness are in the text used synonymously. I am ignoring Subject-consciousness and deal only with Object-consciousness. I may say that I consider ideation as certainly as perception to be a state of object-consciousness. (See Med. Press and Circ., Aug. 30th, 1893, p. 308) If a man in a dream "sees" a black cat that mental state is as certainly objective as is his seeing what we call a real black cat in the day is.

(c) Literally taken, the statements in the text imply that there is a sort of homogeneous consciousness, and that in the first depth of Dissolution, for example, there is a certain quantity lost, corresponding to abrogation of the layer A. and that there is retention of the rest corresponding to intactness of B.C, and D. In writing on so complex a subject it is not possible to be always giving qualifications. I repudiate the implication mentioned, looking on it as an absurdity. For as evolution is a passage from the simple, &c., to the complex, &c., the reverse process of Dissolution is a passage from the complex, &c., towards the simple, &c. Thus in the first depth of Dissolution there is loss of the most complex, &c., and retention of the next most complex, &c. Or more generally and roughly, the deeper the Dissolution the less elaborate is the mentation remaining possible.

(d) Here a question arises. It may be said that in certain cases of insanity there is no consciousness remaining in any of the degrees. I refer especially to post-epileptic states. When. a man, after a slight epileptic fit, acts elaborately and yet quite irrelevantly to his present surroundings, he is said to be unconscious. If this be taken literally the patient is for time a mere automaton, a neuro-muscular machine. Others would infer from the elaborateness of his actions that the patient, commonly said to be unconscious, really retains some degree of consciousness. Each view has consequences. Those who take the first view cannot say that when the patient is comatose after a severe fit there is greater negative affection of consciousness than there was after his slight fits, because they hold that he has no consciousness after the slight ones. Those who take the second view may say that there is greater negative affection of consciousness after the severe fit than after the slight fit. All that we *know* is that the patient on full recovery *remembers* nothing (this is the rule at least) from the

Putting the matter differently we have not only to take into account the dissolution of the one layer A. caused by the disease, but the Evolution going on in the layers B., C. and D., which no pathological process has touched. In every case of insanity, short of dementia, there is a problem in evolution as well as one in dissolution. We may say that "to undergo dissolution," to lose A. for example, and "to be reduced to a lower range of evolution," to B., C. and D. in the example taken, are equivalent expressions.

Dissolution and Evolution in cases of insanity vary inversely—the shallower the Dissolution the higher the range of evolution remaining; conversely the deeper the Dissolution the lower the range of evolution remaining. Correspondingly the shallower the Dissolution the less the consciousness is lost and the more of it remains. In other words the slighter the Dissolution the less the negative mental states and the more elaborate the mentation remaining possible. I will now try to illustrate the duplex mental state in insanities. Suppose a patient imagines, to take one delusion as a sample of his mental condition, that his nurse is his wife. It is not enough to dwell only on the positive element, that he supposes the person attending on him is his wife, for this delusion of necessity implies the co-existing negative element that he does *not* know her to be his nurse (or some woman not his wife). His "not-knowing" is a sample of the result of disease (Dissolution of A.); his "wrong-knowing" is a sample of the outcome of what is left intact of his highest cerebral centres (Evolution going on in B., C. and D.) (*a*)

I now take for further illustration a case of insanity from what I suppose to be a Local dissolution of the highest cerebral centres. When a general paralytic believes he is Emperor of Europe, I submit that this delusion (the patient's belief) arises during activity of perfectly healthy nervous arrangements, presumably those of the posterior lobes and those left intact of the anterior. The disease of the anterior lobes is reponsible for his not knowing that he is X.Y., a clerk in the City.

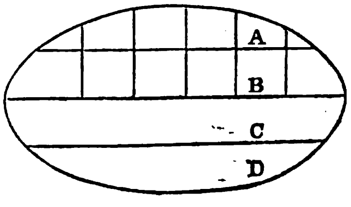
Illusions, delusions, extravagant conduct and abnormal emotional states in an insane person signify evolution, not Dissolution; they signify evolution going on in what remains intact of the mutilated highest centres—in what disease, effecting so much dissolution, has spared. The positive mental states mentioned *imply* the co-existing negative mental states, defective perception, less reasoning power, less adaptation to present surroundings and absence of the "finest" emotions (in comparison with the former, sane, person). To take examples, Any illusion implies that a thing is *not* recognised as it would have been before the insanity, and this means that there is a co-existing negative mental element; any delusion implies that the patient does *not* believe as he would have done before he underwent Dissolution, and this means that there is a co-existing negative mental element. (*b*)

To resume:—In the first depth of Dissolution the negative mental state is slight, the dissolution being very shallow; the positive mental state is very elaborate, the range of evolution remaining being very high. This depth (first degree of insanity) may be symbolised as $-A+B+C+D$. In fact the whole person is now $B+C+D$. The term $-A$ is only given to indicate how the new person, the man insane, $B+C+D$ differs from the former person, the sane man, $A+B+C+D$. Suppose the sane man is X. then the insane man, the new person Y, is $X-A$, that is Y is $B+C+D$.

And here when using the term "new person" for Y, we must urge that what we call his delusions are his beliefs, and most generally his positive mental "symptoms" are samples of a mentation which is only abnormal in contrast with the mentation of the prior self X. (or with that of some arbitrary standard of sanity.)

(B) *Second Depth of Dissolution.* (*Second Degree of Insanity.*)

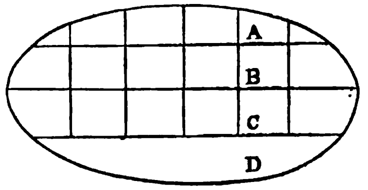
Let us imagine that disease (any pathological process productive of loss of function whether there be destruction also or not) has affected not only A. but B. also.



Now the negative mental element, defect of consciousness, is greater and the positive less; less consciousness is retained. Correspondingly since the dissolution is deeper, A. and B., the range of evolution is shallower, C. and D. This depth may be symbolised as $-A-B+C+D$. The new person is $C+D$.

(C) *Third Depth of Dissolution.* (*Third Degree of Insanity.*)

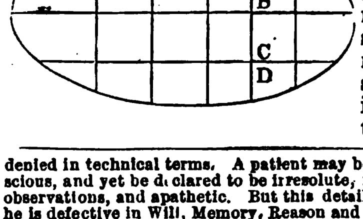
Let us imagine that the layers A., B. and C. have been put out of function.



Now the negative mental element is very great and the positive very little. Correspondingly the Dissolution is very deep; the range of evolution remaining, only D., is very shallow. This depth may be symbolised as $A-B-C+D$. The new person is now D.

(D) *Fourth Depth of Dissolution.* (*Fourth Degree of Insanity.*)

Let us imagine that the layers A., B., C., and D. are rendered functionless.



Here the negative mental affection is greatest, is indeed total; there is dementia. There are no positive mental symptoms; there is no mind or consciousness. There is complete Dissolution, and thus no

---

period of his post-epileptic elaborate action. In the text I speak as if in cases of dissolution consciousness did attend activities of the lower, intact, layers of the highest centres—activities of the lower range of evolution remaining.

(*a*) Of course there is in normal states a rhythm of evolution and dissolution—a going in and a going out of function. I ignore this in the text. There is a big rhythm of evolution and dissolution in healthy people, being awake in the day and asleep at night. Some of the "uses" of sleep are that the highest ranges of the highest centres may be "swept clean" of trivial acquirements made during the day, and that "internal evolution" (evolution going on without interference by or reaction upon the environment) of the lower ranges may be facilitated.

(*b*) It may be said of some cases of insanity that there is no defect of consciousness. But I think we do not always take into account slight degrees of negative affection affection of consciousness; it almost seems to be assumed that above loss, or what is called loss, of consciousness, there are not slighter degrees of negative affection of consciousness. A patient in a lunatic asylum may write letters and occupy himself in other ways, may argue with his doctor about his own case with considerable pertinence. One does not say of such a patient that he has loss of consciousness, but that he has defect, slight defect, of consciousness, Moreover I think of some insane patients defect of consciousness is admitted in popular language, when denied in technical terms. A patient may be said to be perfectly conscious, and yet be declared to be irresolute, forgetful, not clear in his observations, and apathetic. But this detailed statement grants that he is defective in Will, Memory, Reason and Emotion, and since these are the (artificially distinguished) elements of consciousness, the statement amounts to saying that the patient has some degree of negative lower range of evolution remains. Here is what I called "the obvious exception" to the statement that the mental condition in insanities is a double condition, one of a negative and a positive element. In the fourth depth there is no *person*, but only a living creature.

Recapitulation as to Different Depths of Dissolution.

The deeper the Dissolution the lower the range of evolution remaining, and correspondingly the greater the negative affection of mind or consciousness and the less elaborate the mentation remaining possible, until the deepest (total) Dissolution when there is no range of evolution remaining and no mentation going on (dementia).

We must not speak crudely of disease "causing the symptoms of insanity." Popularly the expression may pass, but, properly speaking, disease of the highest cerebral centres no more causes positive mental states, however abnormal they may seem, than opening flood gates causes water to flow, or than cutting the vagi causes the heart to beat more frequently. Disease only causes the (physical condition for the) negative element of the mental condition; the positive mental element, say a delusion, obviously an elaborate delusion, however absurd it may be, signifies activities of healthy nervous arrangements, signifies evolution going on in what remains intact of the highest cerebral centres.

Suppose we compare and contrast the first degree of insanity with the fourth degree. The dementia in 4, no mentation at all, is not a greater degree of the "mental condition" in 1, but only a greater degree of the negative mental element (defect of consciousness) of that duplex mental condition. In 4 there is no positive mental element to compare and contrast with that of 1.

In regard to the hypothesis that positive mental symptoms of insane patients signify evolution going on in lower, intact, ranges of the highest cerebral centres, we have to consider not only the absurdity, but also the elaborateness, of the mentation remaining possible. An insane woman told me that she had seen some cats going in an open boat to meet our Saviour in the air. Nothing could be more absurd, but the statement was as elaborate as the statement of a healthy man who tells us that he went by the ten o'clock express to York to attend a railway meeting. I ask: Is it likely that what this patient said signified activity of any diseased nervous arrangements of her highest centres? (*a*)

To take another case. Alcohol is said to "excite the brain." That from its first action there may be a transient stage of stimulation of the cells of the highest cerebral centres I need not deny. But I submit that the uproarious drunkard is in a duplex mental state with correspondingly double physical states—that more or less of the highest ranges of his highest cerebral centres is out of function; his uproariousness is the outcome of over-activity of the lower ranges of those centres which have not yet succumbed to the poison. Hence we should not say that the alcohol "caused" the condition of which the uproarious conduct was the outcome; it caused only the negative physical condition co-existing with that super-positive condition. The alcohol may be said to be "constructively accountable" for the uproariousness; the loss of function of the topmost layer of the highest cerebral centres which it produces is a removal of control from the lower layers of those centres. Suppose the "uproarious" drunken man drinks much more; he becomes comatose (acute temporary dementia). Now all ranges of his highest cerebral centres have succumbed to the poison; no mentation goes on and there are no actions. Now for comparison and contrast of the four degrees of insanity.

Taking the negative elements, Dissolutions of the four depths, there is -A, than -A-B, then -A-B-C, and lastly -A-B-C-D—correspondingly increasing negative affection of consciousness and finally loss of it. These are things comparable and contrastable. Taking the positive elements, evolutionary ranges remaining, there is B+C+D, then C+D, then D, and finally nothing, no evolutionary remaining—decreasing consciousness and finally no consciousness. Whilst we may say that -A-B-C-D (dementia) is a greater degree of -A, it is absurd to say that it is a greater degree of the condition of two co-existing opposities -A+B+C+D.

(2) SECOND FACTOR IN INSANITIES. THE PERSON WHO HAS UNDERGONE DISSOLUTION.

This factor may seem to need little illustration. It is obvious that the insanity will vary according as the person who has undergone Dissolution of his highest cerebral centres is a child or an adult or an old man, clever or stupid, intelligent or unintelligent, educated (trade, &c., included) or non-educated. At any rate, it is obvious when the Dissolution is but of little depth.

Here has to be considered the question of heredity of insanity. I submit that no one inherits a tendency to insanity in the sense that he inherits a tendency to disease (pathological process) of any part of his brain. He inherits a healthy brain, but a smaller one than the average; I do not mean smaller morphologically, but smaller in the anatomico-physiological sense that he has fewer functional elements in the highest ranges of his highest cerebral centres. He inherits a brain which will "give out" more easily under unfavourable influences than the brain of the average man. (*a*)

(3) THE THIRD FACTOR IN INSANITIES—RATE WITH WHICH DISSOLUTION IS EFFECTED. (RATE OF REMOVAL OF CONTROL FROM RANGES OF EVOLUTION REMAINING.)

The more rapidly the Dissolution is effected the greater is the activity on the range of Evolution remaining. To take extreme cases. The senile dement undergoes Dissolution very slowly. The post-epileptic maniac has undergone dissolution with extreme rapidity. The former is quiet, the latter is very busy. In the former control is slowly, in the latter rapidly, removed from the lower ranges of evolution remaining.

Taking the first Depth of Dissolution for illustration

---

affection of consciousness (of object-consciousness). All this is consistent with his doing common place things definitely, with memory of all ordinary matters and of many long past circumstances, with his talking to the point on simple things, and with his having some interest in striking occurrences; or, in other words, that with some defect of Will, Memory, Reason, and Emotion, there should be persistence of the rest of these so-called faculties—that with loss of "some" mind or consciousness (with some defect of consciousness, there should be retention of the rest of mind or consciousness. For a man to be absolutely unconscious, or synonymously demented, is for him to have no Will, no Memory, no Reason, and no Emotion.

(*a*) If any one supposes that what for distinction one may call primary delusions are "caused" by *disease* of the brain, there are certain "secondary delusions" which surely are not caused by any pathological condition. A patient of mine in the London Hospital had the painful delusion that she was to be hanged; that this delusion (really her belief) was framed during activities of any diseased nervous arrangements of her brain seems to me to be an impossibility. But granting for the moment that it was owing to disease, certain further statements she made—that "people ought to be tried before they are hanged" and that (on hearing the hammering some workmen made in altering a part of the ward out of her sight) a "scaffold was being erected for her"—were rational inferences from her primary "delusion." These inferences were unquestionably her beliefs, and they, at any rate, were not concomitant with activities of any diseased nervous arrangements.

(*a*) Griesinger wrote; "Sometimes we see individuals who, after partaking of a relatively small quantity of spirits and without being in a state of deep intoxication, but retaining fully their consciousness, present a great tendency to commit very extravagant, noisy and foolish acts; a circumstance which may be truly considered as a symptom of predisposition to mental disease." (*On Mental Diseases, New Syd. Soc. Trans.*, 1867.)

we may symbolise the first factor and the third factor. In two patients the symbolisation as to factor 1 is $-A+B+C+D$. But in one of them Dissolution of A. is rapidly effected, in the other slowly; this means that control is rapidly removed from $B+C+D$ in one and slowly in the other. So that in one the layers B., &c., are very over-active, in the others they are more nearly normally active. We may symbolise the two, one as $-A+B''' + C'' + D'$ and the other as $-A+B+C+D$.

(4) FOURTH FACTOR IN INSANITIES.

There is the influence of local bodily states and of external circumstances. A healthy man has muscæ from intra-ocular specks; they seem like moving spots and films in front of him. But suppose he undergoes Dissolution (as in cases of Delirium Tremens) and that there is the first depth of dissolution; then he sees mice and rats. Speaking roughly the muscæ "turn into" those animals for him. The most striking illustrations of the fourth Factor are given by provoked dreams in the normal dissolutions of sleep; cramp in a sleeper's finger developes the dream that a cat is biting his finger.

What we call external circumstances are perhaps artificially separated from "local bodily states." If a man had been reading about kings he might, if he became insane soon afterwards, believe himself to be a king. What was doing just before an epileptic fit may influence the patient's actions in the temporary insanity after it.

COMPLICATION OF FACTORS.

Although it is necessary for clearness to speak of the factors *seriatim*, it is evident enough that each must not be thought of in isolation from the others.

As in different Insanities there are different depths of Dissolution of the highest cerebral centres, as the persons who undergo dissolution are different, as dissolution is effected at different rates and as the local bodily states and external circumstances of different patients are not the same, we may say that every case of Insanity is a "function of four variables." With regard to what we may call the Complications of the Factors, it is of no use speaking of the fourth depth of dissolution—dementia. In this depth there are no longer highest cerebral centres, there is no mind, there is no person, the rate with which dissolution is effected, when that dissolution is established, is of no consequence (a) and local bodily states and external circumstances have nothing to influence. In what follows I shall ignore the fourth depth of dissolution.

Obviously the deeper the Dissolution the less we are concerned with the factors 2, 3, and 4. There is in deep dissolution reduction towards what we may rudely call a general personality, one in which individual peculiarities are more or less effaced—a reduction, still speaking rudely, towards what is common to the race. And in deep Dissolution the rate with which it is effected is of less consequence than in shallow Dissolution, the range of evolution remaining in the former case to be in over-activity from rapid removal of control being less. Further, in deep Dissolution there remains little range of evolution for local bodily states and external circumstances to act on.

We may say that the shallower the Dissolution the more elaborate is the mentation possible, the greater difference does the rate with which Dissolution is effected make in the activity of the lower range of evolution remaining, the more is there retention of "individual peculiarities" and the more do local bodily states and external circumstances influence the mentation still possible.

This must suffice, although many qualifications might be mentioned. The word "elaborate" may mislead. Although speaking generally, the shallower the Dissolution the more elaborate the actions possible, it is obvious that in comparatively deep Dissolution very elaborate actions may remain if the nervous arrangements for them have been (Factor 2) strongly organised, as, for example, manipulations of trade, &c.

I have in the foregoing spoken of insanities as if in all cases the disease producing dissolution were primarily of the brain. But I think that in many cases of insanity the brain suffers secondarily, for example, in acute non-cerebral maladies, such as pneumonia, when they are attended by delirium.

We have to bear well in mind that there are, broadly speaking, two factors in the physical processes corresponding to the mentation of healthy people. I cannot here go fully into this question. A man may have a highly developed brain, but not the full use of it, if the subserving organs (of digestion, circulation, &c.) are not well developed, or have become inefficient. Such a man may have many fine thoughts, and yet no system of thinking; his brain soon falls out of gear when dealing with complex subjects. And I believe that some cases of insanity ordinarily so-called, are owing not to primary disease of the brain, but to failure of the brain, because it is ill-served by the circulatory and other "vital" systems.

I think it is a legitimate hypothesis that the mental disorder from poisoning by belladonna—to take for definite illustration that artificially produced temporary insanity—is mainly owing to failure of the subserving systems (digestion, circulation, respiration) and not entirely, possibly not at all, to direct action of the drug on the so-called "organ of mind" itself. Atropine is known to poison certain nervous elements of the lowest level for regulating the circulatory and other "vital" systems (a) and connections of those elements with the organs of these systems. The cerebral hemisphere will suffer according to the degree of ill-service by the organs of the four "vital" systems thus put in difficulties by the poison. (b) I hope to consider this aspect of insanity on another occasion. (Here is given a qualification to the statements on heredity of insanity when speaking of the Second Factor.)

◆

THE THERAPEUTIC ACTION OF ORGANIC EXTRACTS.

By CHARLES FORBES, M.D., C.M., D.P.H.Cantab.

My object in writing the notes on above substances (Med. Press and Circular, April 18th, 1894) was not to claim any priority to myself of working with cerebrinin or orchitic extract, but to lay before the profession at large the results I have obtained (on certain broad and well-defined therapeutic lines, and in terms as simple and clear as possible) with a particular class of preparations of these extracts. I refer to "tabloids." These I have already stated my reasons for adopting after a somewhat lengthy trial clinically of other preparations, such as organic liquid extracts. We must all admit, however, that the merit of pointing out this line of therapeutic work gilds the name of the late learned experimentalist Dr. Brown-Séquard, who initiated all discovery in this direction: I mean, of course, the practical application of extracts as remedial agents in what had been deemed previously almost incurable diseases, such as pseudo-hypertrophic paralysis, &c. In his "Mémoires" he pointed out some of the diseases in which he thought they might prove of service. His methods, however, have met with no great success in the hands of English physicians. So it will be clearly seen that all our claims to the *κυδος* of discovery are thus invalidated, except so far as we shall be enabled by our experience and investigations to increase the list of morbid conditions for which we may use as preventive, palliative, or curative weapons any of these extracts, viz., cerebral, orchitic, ovarian, thyroid, or pancreatic, and formulate at least their apparent therapeutic action and further to elucidate more clearly to what principle or group of principles their activity as medicines may be due. I must now thank Dr. Felkin for correcting my statement as to date when the abstract of his paper on organic extracts was read in Edinburgh in his paper, "Notes on Organic Extracts" (Medical Press, May 23, 1894, p. 535-6), and cordially concur with his expression that a full report of all cases with an exact account of the minutiæ of phenomena occurring in patients taking these agents would go far to clear away some of the doubts as to the utility of these extracts. Dr. Bramwell has clearly shown us the value of thyroid tabloids in myxœdema, &c., in the *British Medical Journal*, and Dr. Clouston and Mr. C. F. Beadles have also given their testimony in able papers as to its effect on the mental affections coincident with the myxœdematous symptoms.

(a) I mean so far as we are concerned with it in the present inquiry.

(a) To take a slighter, but more chronic case, one we do not call insanity. I attribute the neurasthenia in Graves' malady (the so-called "emotional condition" and "mental instability" of the patient) to imperfect mental work of the "four systems" consequent on negative lesions of elements of the lowest level representing those systems. (So too for ordinary cases of neurasthenia.)

(b) It may, however, be asked how it is that there are *visual* illusions or hallucinations in cases of belladonna poisoning. In the first place most of the elements of normal mentation are visual ideas, and this will be so in the abnormal mentation of insane persons. But in the poisoning by belladonna, of young persons at least, the state of the intro-ocular musculature has to be considered. In two cases recorded ("Lond. Hosp. Reports," vol. iii), one by Dr. Gossett-Brown and one by Dr. Fraser, the pupils were widely dilated, and presumably the ciliary muscles were paralysed. Hence there was a peripheral, ocular, condition influencing the parts of the layers of the highest centres remaining in activity, one likely to affect visual ideation. In one of these cases objects appeared to the patient as a long way off—a very significant thing when it is remembered that uncomplicated paralysis of the ciliary muscle makes objects appear smaller. It is not necessary to suppose that in these two cases the poison acted especially on any "visual centres" of the cerebral hemispheres.

I am of opinion that this drug would also be useful in cerebral anæmia from various causes. The reports of cases I have mentioned would doubtless assist us in our necessary differentiation of the various properties of the extracts, but this time has not arrived yet, although the successes of Drs. Bramwell and Felkin have been marked when using suppositories, &c., (Burroughs and Wellcome) still the great plea I have in favour of their use (I refer to organic extracts) is their activity as medicines of which as yet we do not know the full value. Dr. Felkin seems to agree to the main conclusions in my paper. He quotes the case of a lady (Medical Press, May 23rd, p. 536—Masturbation =nymphomania?) where he says orchitic extract failed but cerebrinin succeeded. Her case seems to have been most inveterate, and the results of treatment point most surely to the fact that the seat of mischief was in the brain where the local irritation was generated and so to speak causing the habit reflexly. Whereas the first case he quotes as cured by orchitic suppositories was clearly due directly to local irritation tending to prolong the practice of onanism. This is commonly seen in boys under ten years, should they have an elongated prepuce. Again, he says orchitic and ovarian extracts are erratic in their effects. This may appear to be true, but, of course, much depends on the selection of cases, and the preparation used, and this is notably the case in connection with the liquid extracts. And now as to the use of thyroid gland in "Leprosy." This should be tried by practitioners in India and China, and should it prove successful in the smallest degree the matter should at once be taken up by our Government and pushed to its utmost, as it will be perhaps the greatest boon ever conferred on suffering humanity. Moreover, we are, indeed, justified, by the marked success gained in certain diseases, in experimenting with each of these extracts in whatsoever complaints we may judge will afford us any chance of success! Dr. Felkin in his paper (May 23rd, 1894, p. 536) seems inclined to the theory that there is *one* definite element contained in all the glands, and which *element* should be available in a wide range of diseases. This may be true, but it has not been corroborated by searching investigations which, when in a more finished stage I am of opinion will give as their consequence some such results as the following words express:—"That each gland, &c., possesses its own principle or group of principles (which perhaps may be classed as globulins?), but that all these principles probably, though thus differentiated, belong to one and the same complex group of organic chemical compounds (may we term them albumoses *pro tem.* for want of a better name.") In the near future I trust we may be able to differentiate still further these complex substances and then afterwards proceed to describe the properties, chemical and therapeutic, of each separately. At present, my belief is based on the fact that their very complexity is perhaps the greatest cause of their activity, and that when we succeed in splitting them up into their various constituents we shall get different results with them as medicines. However, this remains to be proved. Just now our knowledge of their utility must be confined to clinical effects. Dr. C. H. F. Routh, in his paper on "Castration in Females" (Medical Press, May 16th, 1894, p. 511) refers to *spermine* as being the active *element* in the ovary apart from its ovulatory function and implies that it is common to other glands as well. Perhaps it may be extracted from testicle, but my own work throws some doubt on his statement that it is found in any other glands. If this were established as a certainty, spermine would be a simple answer to a series of recondite questions, but I fear we cannot so easily cut the Gordian knot of our difficulty! Dr. Felkin, in his paper above quoted, calls attention to the practice of partial castration in Africa, leaving the castrated one with virile powers. Similar mutilations are carried on among the aboriginal tribes of Australia, and the same phenomena are developed by the partial destruction or alterations in the normal tissues of the testicle by general or local disease, such as constitutional syphilis, chronic phthisis, local tubercular disease, and orchitis from injury, gonorrhœa, &c. Just a word as to ovarian extract. This is a very active preparation, most efficient in relieving the troubles at the menopause or following ovariotomy, especially when only one ovary is removed. These troubles are mentioned by Dr. Routh in his conclusions (Medical Press and Circular, May 16, 1894, p. 511). They may be functional disorders of the nervous system, &c., but these may become organic; melancholia, and chronic mania sometimes having been noted; but this extract will, perhaps, also be more useful in functional nervous complaints produced by some irritative action to be referred to the organs of generation. As a conclusion, I may remark that both the testicle and ovary possess some function apart from the manufacture of semen and ova, which has not yet been clearly described by physiologists. I trust that these notes may prove a potent plea that will induce many learned practitioners to investigate this subject which will, I am convinced lead to results highly beneficial to the human race.

◆

THE TREATMENT OF NEURALGIA WITH ANALGEN ($N HO OC_6 H_5 H$).

By GEORGE FOY, F.R.C.S.,

Surgeon to the Whitworth Hospital.

Before the growth of cinchona in the East Indies became an assured success, the question of the quinine supply became a very serious one. Substitutes were sought out, the other alkaloids of the cinchonas were tried and other products of the vegetable kingdom such as salicin. About this time coal tar products were first popularised, in many different forms organic chemistry opened up a new field of research. The production of organic bodies artificially by the synthetic process was accomplished in numerous cases, and there were hopes that quinine would soon be included in the list. The hope was strengthened when it was demonstrated that quinine was a derivative of a simpler basic body, to which the name quinoline or chinoline was given.

Quinoline has the formula $C_9 H_7 N$. Working with this base Friedlander and Gohring produced a large number of compounds with methyl, phenyl, and so forth. Quinoline was also prepared from the cinchona alkaloids. And quinoline and its salts and compounds were found to possess the antipyretic, antiseptic, and tonic properties of the alkaloids of cinchona. Those who had taken up the subject were fascinated with the prospect of producing quinine, but always met with disappointment. Other chemists working out the aromatic series of organic chemistry produced salts, which, judging from their chemical composition they believed would be found to have therapeutic properties resembling quinine, and in the early years of the eighties many of these new drugs were introduced. Derivatives of the aromatic group were not always safe, they had a depressant action on the heart, and some of them were toxic, and the majority of them were prone to be followed by a rash which alarmed the patient, in many instances. From depressant effects compounds of the quinoline series were free. Physicians came to prefer them, and chemists came forward to supply the demand.

The latest, and, I think, one of the best products of the series is "Analgen." Its chemical title is a very long one, and its composition is very complicated. The manufacturers, by giving its composition and method of production, remove it from the list of secret remedies, a not unimportant fact for prescribers. The chemical formula given is $N\ HO\ OC_6 H_5 H$, and its chemical name is Ortho-aethoxy-ana-monobenzoy-lamido-quinoline. It is a white crystalline powder, insoluble in water, soluble in acids, readily soluble in hot, and sparingly soluble in cold, alcohol. As a criterion of its purity, it melts at 208° C., and leaves no residue when burned on a sheet of platinum. From experiments on dogs it has been determined that analgen is non-toxic, and when given in large doses the kidneys remained unaffected. Not unfrequently, however, the urine becomes a cherry red colour during the use of the drug, a discolouration caused by the action of the uric acid on the separated benzoyl group of the analgen, a purely chemical reaction of no physiological or pathological importance; neither blood, albumen, nor sugar were found in the urine of healthy persons to whom the chemical was administered, a statement which agrees with my experience after a trial of the drug for close on twelve months.

I obtained my first supply from Messrs. Thomas Christy and Co., of Lime Street, London, for a patient who had a violent facial neuralgia, and who for years found relief from the use of bromides; these in time lost their effect, and analgen was tried, at first in five-grain doses every three hours, but without any relief. I now decided to make the dose ten grains, and repeat as before; the effect was marked, the intense supra-orbital pain ceased after the second dose; the intolerance of light and sound disappeared, and the patient was able to resume her ordinary household duties. Still wishing to keep on the safe side in dosage, I ordered seven-grain doses for my next patient, a married woman, æt. 40, who for the past twenty years has suffered from toothache, neuralgia, and so forth, but in whose case there was no history or trace of syphilis. She took six such powders with little or no effect until, in her despair, she took two powders at one time. The fifteen produced a marked lessening of the pain. She repeated the double dose in three hours, and about an hour afterwards she declared that all pain had ceased. My experience of the drug is limited to about two hundred cases; of these the majority were neuralgic, and in every case I found that the drug must be given in full doses if relief is to be obtained. Except in the case of children of twelve to fifteen years, five-grain doses gave no results. The smallest effective dose for adults was ten grains; the largest dose I have given was fifteen grains, and the dose in every case was ordered to be repeated in three hours. I am, however, inclined to think that the dose should be repeated every two, instead of every three, hours. Migraine is quickly got rid of by a fifteen-grain dose, as is cephalalgia. For rheumatism the effects of analgen are more marked if it is combined with tartrate of soda in drachm doses, or if its use is preceded by the old-fashioned black draught and blue pill. In old-standing cases of sciatica I have not found the drug very effective—but what drug does benefit such cases? The insolubility of the drug in water is a drawback to its general use, but patients really suffering acute pain make no objection to swallow powders, or, indeed, any form of medication that offers hopes of relief.

As an anti-neuralgic remedy analgen is a distinct gain, and very welcome to the medical profession. Abroad it has been largely used, and the reports of its therapeutic effects are most favourable. Dr. Goliner, of Erfurt, reports (*a*) four cases, including visceral neuralgia, tabes, lues, and trifacial neuralgia. Dr. Treupel, of Breslau, recommends it for rheumatic gonorrhœa, articular rheumatism, and sciatica. A remarkable case of its beneficial effects in that most obscure of nervous diseases, agoraphobia, is given by Dr. Keberlet. (*b*) He prescribed fifteen grains of analgen morning and evening, and applied a cold embrocation to the patient's breast. "In fourteen days the nervous affection was effectually cured, to the great relief of the patient."

I may just add that in no case in which I prescribed analgen has the patient complained of singing in the ears, deafness, fulness in the head, nausea, nor have I known of a single case in which any rash followed from its use.

Selected Prescriptions and Therapeutic Notes.

150.—To Allay the Itching in Urticaria:—

℞ Hydrarg. perchloridi, gr. iss;
Chloroformi, ♏xx;
Glycerini, ʒij;
Aq. rosæ, ad ʒviij.
M. To be dabbed on the affected parts.—BURGESS.

151.—"Carbolised Collodion":—

The following formula is a good one for the preparation of "carbolised collodion":—

℞ Acidi carbolici,
Olei ricini, āā ʒss;
Collodii, ℥j. M.

152.—For Vaginismus:—

℞ Iodoformi, gr. xv;
Extracti belladonnæ, gr. viij.;
Ol. theobromæ, q.s.
M. For one suppository. To be used at bedtime.—LUTARD.

153.—Useful in Alopecia Areata:—

℞ Resorcin, ʒiss;
Ol. ricini, ʒiss;
Sp. vin. rectificati, ʒv;
Balsami peruviani, gr. viij.
M. To be applied locally.—HAZARD.

(*b*) "Der Praktische Aerzt."

Clinical Records.

HOPITAL SALPETRIERE, PARIS.

Case of Pedicellate Adenoma of the Posterior Wall of the Stomach—Ablation—Suture of Walls of the Stomach—Recovery.

Under the care of Dr. Chaput.

(Reported by our French Correspondent.)

A man, æt. 64, was admitted to the Salpêtrière on April 4th, 1894. He was extremely cachectic. No important hereditary antecedents. His present illness began nine months ago. He had first indigestion, colic, and flatulence. Three months ago he vomited during two days much black fluid, resembling tar. Since that date has suffered from dull pain in the epigastrium; has lost appetite and mostly vomits after feeding. He has been aware for three months of the appearance of an epigastric tumour. He has become extremely thin since the commencement of the dyspeptic symptoms.

There is in the epigastrium a large tumour visible externally, but more definable on palpation. It is limited below by a line passing horizontally through the umbilicus, above by the border of the false ribs, and another horizontal line passing five fingers' breadth above the umbilicus, externally by the costal margin, and forward it encroaches a finger-breadth on the median line, to the right of which it is prolonged. The tumour is hard, and does not fluctuate, and is sonorous to percussion; it is mobile transversely, less so vertically. It is painful, and tender to the touch. When the abdominal muscles are contracted the tumour disappears behind them. There is no sign of dilatation of the stomach; no enlarged glands discoverable.

In presence of the symptoms—digestive troubles, sanguinary vomiting, tumour, cachexia—cancer of the stomach was diagnosed.

M. Chaput hesitated at first to interfere, because of the cachectic state of the patient; he later decided to operate on consideration that the pylorus was probably intact, as the stomach was not dilated; that the tumour was situated on a level with one face of the organ, and that its ablation would be much less dangerous than that of a cancerous pylorus.

The operation was performed on April 18th. The patient was fed on milk only for several days before, and was kept without food from the previous afternoon. A median laparotomy below the umbilicus was performed. The stomach was then drawn forward. The anterior wall was healthy and glided over the surface of a more deeply-placed tumour. This wall was incised for a distance of 12 centimetres equidistant between the large and small curvature.

The tumour within the stomach showed a lobulated surface not ulcerated but covered by white mucus. The stomach was well washed with boiled water. It was then discovered that the tumour sprang from the posterior wall by a short thin pedicle, but of which the line of attachment to the stomach wall measured about 8 centimetres.

The pedicle was seized by long forceps, which were made to include some centimetres of sound adjacent surface, and divided. The peritoneum was not wounded by this procedure except in the left half of the incision; in the right half the mucous membrane alone was incised. The wound of the peritoneum was closed with a continuous suture and the stomach was closed.

The patient made a rapid recovery without fever or other untoward symptom. Examination of the tumour revealed the presence of numerous glandular cavities with a single layer of cylindrical cells and an interstitial tissue containing few cells. These characters of the growth, together with the existence of a pedicle, and the absence of ulceration, led to the belief that it was an adenoma rather than a true cancer.

The patient was shown at the Societé de Chirurgie on May 23rd, 44 days after operation. He had gained 6 kilograms in weight, and was in perfect health.

The Woman's Medical College of Pennsylvania have just turned out fifty women who have received the degree of Doctor of Medicine.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, May 11th.

The President, Dr. Walter G. Smith, in the Chair.

AN UNUSUAL CASE OF EXOPHTHALMIC GOITRE (GRAVES'S DISEASE).

Dr. Craig exhibited a patient and read a paper on the above, the subject being a girl, in whom the eyeballs were markedly prominent and the lower half of the bulbar and palpebral conjunctiva of each eye formed a red protruding mass, which buried the edges of the lower lids completely beneath it. The lower portion of each cornea was ulcerated, there was no anterior chamber, and in the right eye a small mass which appeared to be the obtruded lens lay on the swollen tissues. The upper lids were freely movable, and the conjunctiva underneath was red and congested, but free from chemosis. The sight was gone, except that the patient could distinguish light from darkness, and the pain was so intense that sleep had been impossible for nearly a week. The full paper appeared in our last issue. In the discussion that followed its reading,

Sir Wm. Stokes said he had seen her shortly after her admission to hospital. The chemosis of the conjunctiva and the exophthalmos, especially the former, were much more striking then. As regards the surgical treatment of cases of this class, he suggested, in lieu of thyroidectomy, which was always a serious and difficult operation, the exposure and division of the isthmus of the thyroid body, He had performed this operation in three cases of goitre, in two of which a marked and beneficial result took place, while in the third case no change took place. The size of the thyroid became much less in two of them.

Dr. H. C. Tweedy said that many years ago he had seen inunction of red mercurial ointment tried in one of these cases, with the result that the patient's sufferings were much increased.

Dr. W. J. Thompson asked what line of treatment had been adopted in the present case. He had heard that in some cases there had been observed *post-mortem* changes in the inferior cervical ganglion.

The President said that it was worthy of note that there had been no history of a fright previous to the development of the disease. Many cases had occurred immediately after the Franco-Prussian War. This is interesting, as it may indicate the direction in which to look for the solution of the pathology of the disease. The chemical theory was a new one, and it showed that we might have diseases caused by a plus and minus derangement of the gland. It did not, however, explain the much greater frequency of the diseases affecting the gland in the female. Were we to assume that the metabolism of the female was different from that of the male body. As regards the treatment spontaneous recovery was not so rare as might be concluded from reading the text-books. Some years ago he had seen a young woman, in consultation with Dr. Ball, and she then appeared in imminent danger of dying. She subsequently got quite well. He wished to know had ligature of the arteries going to the gland been tried with a view to, as it were, starve it.

Dr. Craig, in reply, stated that, in regard to Sir Wm. Stokes' suggestion that in some cases division of the middle lobe might do good, this procedure was only of benefit in cases of goitre but not in cases of exophthalmic goitre. The superior and inferior thyroid arteries had been ligatured but without much good result. As regards drugs, belladonna, and ergot he believed to have been the ones most generally found useful. He had applied to the conjunctiva of his patient's eyes, to remove the local affection, resorcin with some good result, and silver nitrate with less effect.

NOTES ON CASES OF THE SEVERE TYPE OF INFLUENZA.

Dr. Burgess commenced his paper with the queries: 1. Are severe cases merely neglected forms of the common form of the disease. 2. Are they of the nature of malignant types of fever attacking internal organs primarily.

3. Is the medical treatment, beyond relieving the accompanying neuralgia, of any use. 4. Does one attack confer an immunity. The first case was one of adynamic pneumonia in a lady, æt. 51, with extreme cyanosis, subnormal temperature, and rapid death. The second was more protracted, the point of interest being the extensive consolidation of the right lung, without breath sounds or vocal resonance—the massive form of Grancher; also described by Skoda. Several exploratory punctures were made in the case, without disclosing any fluid. The third was a milder type in the beginning, but was following by gangrene, evinced by fœtid sputa and other signs; the identity was pointed out with the gangrene du poimon curable Saseque. The case ran a favourable course under treatment. The fourth was a case which presented peculiar features; it was one of rapidly-spreading pneumonia of the left lung, ending with copious discharges of pus by the mouth. In the early part there was high tympany over the upper left lobe. The author alluded to the different explanations given of this sign by Stokes, Williams, Gee, Skoda, and Guttman, and stated that although not uncommon in pleurisy, its existence in pneumonia, so exaggerated was rare. The site of the abscess was doubtful; there was no pneumo-thorax, yet the quantity and character of the fluid simulated empyæma. Dr. Burgess was of opinion that one attack had a protective tendency, and gave facts to support his belief.

The **President** said that he agreed with Dr. Burgess that post-influenzal pneumonias were peculiar. They lacked the characteristic rusty sputum, crepitus over the lungs, and were frequently complicated by limited pleural effusions. The bandbox sound he frequently observed in cases of pneumonia and of pleural effusions. As regards the treatment nothing was of much avail, except in the early stage, when you could lower the temperature and relieve the headache. Careful nursing, careful feeding, and rest for a sufficient length of time were what were needed after this.

Dr. W. J. **Thompson** said he had attended a gentleman who, in 1892, had a moderate attack of influenza. In May, 1893, he was seized with chilliness, and his temperature rapidly rose to 106°. He had cyanosis of his face, headache, and pain in his back and legs. He treated him with large doses of antipyrin and salicylate of soda, as well as some carbonate of ammonia and digitalis. His temperature in a couple of days had fallen and he recovered.

Dr. **Craig** said that he had frequently noticed that the apex and anterior parts of lungs were affected in pneumonia following influenza. He relied on stimulants very much in the treatment of these cases, especially in people past middle life.

Dr. **Burgess** briefly replied.

The Section then adjourned.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, May 17th.

The President, Mr. **George Eastes**, in the Chair.

CASE OF SYPHILITIC LARYNGITIS.

Mr. G. C. **Wilkin** showed a patient, æt. 38, a married woman, suffering from syphilitic laryngitis, associated, when first seen, with consolidation of the apex of the right lung. The case came under his treatment at the London Throat Hospital, on February 6th last. There was no family history of phthisis. She had had two miscarriages and no children. Last August she had an attack which was described as "Erysipelas of the head and face." The throat then commenced to be troublesome. *Examination of Larynx* showed swelling of epiglottis. The false vocal cords were greatly swollen, meeting completely in anterior half. *Examination of Thorax* revealed dulness of right upper lobe back and front. Increased vocal resonance, and pectoriloquy above spine of scapula on right side. The sputum contained no tubercle bacilli. The examination having been made on three separate occasions. The lung symptoms entirely cleared up under a mixture containing iodide of potash and liq. hyd. perchlo. The laryngeal swelling also gradually subsided. The cough in this case had been very troublsome to treat.

The **President** said that he had found great benefit follow the use of syrup of codeia in some cases of severe cough. He also quoted Dr. Sydney Phillips who had brought forward a case of syphilis associated with high temperature which fell directly iodide and mercury were exhibited.

Dr. **Illingworth** submitted that in view of the chemical change which is immediately effected on the addition of iodide of potassium to solutions of the perchloride of mercury, it is not scientific accuracy to describe cures as being effected with "perchloride and iodide." They should be described as being effected with "solutions of the biniodide" in greater or less excess of potass iodide. Furthermore Dr. Illingworth pointed out that the same excellent effects as a curative agent were to be secured in all the other specific febrile disorders, as well as in this particular one, syphilis, by solutions of the biniodide.

PIGMENTATION OF CICATRIX AFTER OVARIOTOMY PERFORMED DURING PREGNANCY.

The interest of this case—brought forward by Dr. **Boxall** lay in the marked pigmentation which had taken place in the scar of an ovariotomy wound. The patient was 25 years of age and of fairly dark complexion. When she first came under observation last summer, there was a swelling in the lower part of the abdomen on the right side, reaching one inch above the level of the umbilicus. Since the swelling first attracted attention nine months previously, it had gradually increased in size, had perceptibly shifted its position from time to time, and had recently become painful. By examination *per vaginam* it appeared that the uterus was enlarged to the size of four months' gestation, though only two months had elapsed since the last menstrual period. The breasts gave no distinct evidence of pregnancy. On opening the abdomen by a median incision the tumour was found to be an ovarian cyst springing from the right side of an enlarged uterus with a long and twisted pedicle. After removal of the cyst the ovary on the opposite side was examined and found to be bulged in one situation as by a large corpus luteum; otherwise the left appendage was healthy; it was consequently retained. The operation was performed just in the middle of pregnancy. When the patient left the hospital three weeks after the operation, there was no appreciable pigmentation of the scar; but about a fortnight later it became deeply pigmented, almost black, and every stitch-hole also. The pregnancy went on to term. The pigmentation has been fading since, but is still quite distinct.

Mr. **Alban Doran** wished to hear Dr. Boxall's opinion about pigmentation in the middle line. It was often associated with pregnancy, but was sometimes seen in sterile women or even in men. Among the patients in a lying-in-hospital at Bordeaux, Mr. Doran noted that the line often extended above the umbilicus. He asked if Dr. Boxall had ever observed pigmentation in abdominal cicatrices situated elsewhere than along the linea alba. He had not found that pregnancy after abdominal section specially predisposed the subject to pigmentary deposit in the cicatrix. In January, 1892, Mr. Doran removed the appendages, much diseased from chronic inflammation, in a case of rapidly growing fibroid. The patient was a fair-haired, sterile woman, æt. 39. Within twelve months the skin along the abdominal scar became deeply pigmented and remains so to this day.

Dr. **Boxall** in reply to Mr. Doran's interesting remarks, pointed out that in pregnant women of dark complexion it was by no means unusual to find that the pigmentary deposit in the middle line of the abdomen extended above the umbilicus, occasionally, even as high as the ensiform cartilage; and that, in doing so, the line divided into two below the navel and joined again above it. A similar pigmentary line undoubtedly sometimes occurred apart from pregnancy; but having made no special observation on the subject, he could not say whether it took place in connection with the growth of uterine fibroids. It was interesting to note in the present instance, that, though the wound was made at the period of pregnancy when the deposit of pigment is usually most active, it was not till some weeks later and after the wound had completely healed that the pigmentation took place; and further, that the middle line above and below the scar was all but free from pigmentation, and that the marks of the stitch-holes, one inch away on either side, were as distinctly mapped out by pigment as the scar of the incision in the middle line. He thought it possible that any scar in the abdominal wall might become pigmented if pregnancy subsequently took place, for he had occasionally observed that even the striæ produced by the stretching of the skin in one pregnancy had become pigmented—not merely coated with dirt that would wash off—during a subsequent pregnancy.

UNINTENTIONAL POISONING BY STRYCHNIA.

The President related particulars of a case of unintentional poisoning by strychnia, which had been prescribed by a medical man in the form of liq. strychniæ in a mixture combined with bi-carbonate of sodium. The soluble sulphate of strychniæ had been thereby decomposed and replaced by the insoluble carbonate which became deposited as a sediment. The bottle was not shaken whilst the first eleven doses were taken, so that the last dose contained far more than the normal dose of strychnia. After swallowing this, the patient was quickly seized with severe tetanic spasms. Ipecacuanha wine and hot water were given, and vomiting produced, and the stomach was washed out with warm water. The patient recovered in the course of about half-an-hour.

ADENOMA OF THE BODY OF THE UTERUS.

Dr. Boxall related a case of adenoma affecting the body of the uterus. The patient is 59 years of age, a widow, who for five or six years had suffered from irregular hæmorrhage from the womb, associated with a tumour in the lower part of the abdomen. Her general health had not appreciably suffered except for the loss. A year ago she consulted an eminent gynæcologist, who regarded the case as one of uterine fibroids and prescribed ergot in full doses. The medicine failed to check the almost continuous loss. On examination the irregular mass felt by the abdomen gave the impression of uterine fibroids. The vaginal examinations confirmed this impression, for the mass was obviously an enlargement of the body of the uterus and was freely mobile. The cervix was healthy. Rest and ergot failing to give relief and the loss increasing, it was decided to dilate the cervix and to explore the cavity of the womb under an anæsthetic. It was then found that the main portion of the mass was composed of material the consistence of brain-matter, which broke down and bled freely when touched, apparently springing from the posterior wall and fundus, but whether in the form of a polypus or not it was impossible to determine. By means of the curette as much as possible was rapidly removed. The *débris* deprived of blood weighed 2lbs. 10ozs. The loss ceased. For a fortnight there was a slight discharge tinged with blood, but none at all for the last six or seven weeks. The uterus, still irregular in shape, contracted down to the size of a ten weeks gestation, and is now freely mobile on manipulation. A small portion of the mass was preserved for microscopic examination, and on section shows nothing but typical tubercular glands lined by a single layer of columnar cells without proliferation and possessing a distinct lumen. The specimen was exhibited.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, June 1st.

Dr. Donald Hood, President, in the chair.

Clinical Meeting.

Dr. Scanes Spicer showed a case illustrating

THE RADICAL CURE OF FŒTID SUPPURATION OF THE NOSE

by free opening, curettement, and drainage of the maxillary antrum. The patient, a young man, came under treatment in July, 1890; there were polypi in the right nostril and discharge of pus from under the middle turbinated bone. The polypi were removed in November, 1890. On Dec. 27th the antrum was opened through a tooth socket and a plate adapted. On May 27th, 1892, as the foregoing treatment and antiseptics had proved of no avail, the antrum was opened in the canine fossa and freely curetted. The patient was very ill for some time, losing two stone in weight in a few weeks; leaden spigots were used, but in April, 1893, one was inadvertently pushed into the antrum. The opening into the canine fossa was then enlarged and a free opening made into the nose in the inferior meatus. The patient regained his normal weight, and had been free from any symptoms for one year.

Mr. Lake referred to a similar procedure adopted abroad.

Mr. McAdam Eccles showed a case of

PROBABLE DEPOSIT OF URATE OF SODA IN THE SCROTUM.

The patient had suffered with repeated attacks of gout, and had tophi in the ears. The testes were normal, the disease had been present and progressive 3½ months, and the skin of the scrotum now presents ragged openings, the edges are undermined, the floor is formed by a hard and fixed yellowish white mass, quite painless. Mr. Eccles had not put him on antisyphilitic treatment, though he believed this to be specific in charactor.

Dr. Clemow quoted a similar case in which a cure was quickly accomplished by biniodide of mercury treatment.

Messrs. Bidwell, Lloyd, and Atkinson were also of opinion that the disease was specific.

Dr. Eccles also showed two cases of subcutaneous nodules in rheumatic subjects.

Mr. Bidwell considered the nodules to be fatty in one case, with which opinion Messrs. Lloyd and Atkinson concurred. Mr. Bidwell showed a man, æt. 27, whom he had shown in November last with a large syphilitic nodule on the left humerus; since then he had spontaneous fracture, and the fracture was explored by free incision. No evidence of sarcoma being found, the wound was cleaned, and the future treatment, which ended in recovery, consisted of prolonged rest and the internal administration of iodide of potassium. Mr. Bidwell showed a girl, æt. 17, suffering from congenital syphilis. She presented patches of ulceration on both ankles and also on the chest; they much resembled scrofuloderma.

Drs. Abraham and Lloyd took part in the discussion.

Dr. Morgan Dockrell showed a case of rodent ulcer of twenty years' duration treated by resorcin. The patient persistently refused operation, and had improved markedly under the external use of resorcin.

Dr. Abraham said he had known of cases which had been cured by zinc ointment.

Mr. Bidwell said he was in favour of removal where possible.

Dr. Dockrell also showed a case of mycosis fungoides. The disease commenced eight years ago after probable psoriasis; it now presented well-marked erythematous scaly patches and fungating masses in the lumbar region and on the arm.

Mr. F. P. Atkinson read the notes of a case of multiple lipomata.

Dr. Abraham showed some cases of skin disease.

France.

[From our own Correspondent.]

Paris, June 9th.

Depopulation and Alcholism.

The depopulation in France has been the constant theme of late years of both professional and lay journalists. France is being depopulated is the universal cry, and statistics seem to give support to the national complaint. In 1789 France was considered the most densely populated of European countries, and represented 27 per cent. of the total European population. While to-day she only represents 12 per cent. The excess of the death-rate is to be found in the infantile population. Within the last ten years 42,000 children were stillborn, and each year 240,000 children between the ages of one year and five years die, so that a German said that France loses every year a battle.

The causes of this progressive depopulation have been the object of active research, and a long list was drawn up, national immorality taking the first rank, then poverty, selfishness, *fin de siècle*, inequality of sex. It is certain that immorality is a powerful factor in the depopulation, as the paternity of a child born out of wedlock is a problem which the law in France refuses to solve, so that the seduced girl has no resource than that of either accepting her situation or that of suppressing the cause of her shame, either by infanticide, not uncommon, or killing the germ at a certain period, which is still common. If, however, animated by more worthy sentiments, the girl desires to provide for her child two courses are open to her, either to put it out to nurse and try to pay for it out of her more than modest wages, or hand it over to the town to take charge of, and in this case also the infant is sent out to the country. The result is very frequently identical, the child dies, unless endowed with a more than ordinary robust constitution. Baby farming in France is as lucrative as it is general, but the system increases the mortality of the children to a frightful extent.

A great deal might be said on the causes of the number of illegitimate births in France, which is, however, far inferior to what it might be if abortion were not so frequently resorted to, but the impossibility in a legal sense of identifying the father is one of the chief reasons. A movement is being made in this direction by a number of influential and right-thinking men who are addressing strong appeals to Parliament on the subj ect.

Amongst the many causes of the depopulation by increase of the mortality is certainly that of alcoholism, which is taking fast root in the country. Hitherto France was considered a sober country, the good wine which was so abundant in former years was regarded as a sufficient beverage; not so now. The invasion of the destructive phylloxera reduced in enormous proportions the production of the vineyards, and to supply the demand a manufactured wine, charged with impure alcohol, was furnished to the people, which played havoc, as may be imagined, with the constitutions of the consumers. Besides, absinthe, the worst of all drinks, became the favourite beverage of the lower classes, so that to-day France is considered on the question of drink in no way superior to England. Drunkenness is one of the causes of an impure and unhealthy posterity. It is well known and proven that the simple condition of drunkenness at the moment of procreation is sufficient to cause a mental and physical inferiority in the children, and the same may be said of those who habitually indulge in alcoholic stimulants, although they may not be drunk at the time of the physiological act. Dr. Legrain, head physician of a Paris asylum, has furnished some striking statistics on this subject. He selected 215 alcoholic families, represented by 819 descendants, with the following result:—

37	premature births.
16	stillborn.
121	premature deaths (generally convulsions).
38	cases of physical debility.
55	cases of tuberculosis.
145	cases of mental derangement.
412	

The remainder comprised a large number of epileptics, hystericals, idiots, &c. One of the causes of the depopulation of France is assuredly alcoholism. According to official statistics for the year 1892, the large amount of 1,735,369 hectolitres of alcohol were consumed, or nearly forty million gallons.

Progress of Cremation in France.

The average number of cremations in France for the first three months of the current year was ten a day, an increase of about twenty per cent., as compared with the same period of last year. In this connection it should be remembered that the facilities for cremation are much greater than is the case in England. The perfect crematorium at Pére la Chaise, in Paris, renders cremation practically as convenient as earth burial, whereas Woking is some distance from London, and there is no other crematorium nearer the metropolis than that in Manchester

Germany.

[From our own Correspondent.]

Berlin, June 8th.

The Treatment of Pelvic Abscess.

At the Medical Society's meeting of the 2nd inst., Dr. L. Landau gave an address on this subject. He said that with the perfection of gynæcological *technique*, gynæcological diagnosis, as regarded the individual operations had not advanced with great pace. For, first of all, diseases had to be discovered for given operations; and in the second place a large series of diseases of unequal importance had been grouped together under collective names, and had been frequently submitted without discrimination to a single operative treatment. This was especially the case as regarded pelvic suppurations, where the usual diagnoses: pelvic abscess, pelvic suppuration, adnexitis, were used without distinction for simple non-suppurative inflammation in the tubes or ovaries, or peritoneum, as well as for multiple extra- and intra- peritoneal abscesses. He had above all endeavoured to fix an exact pathologico-anatomical basis and a rational division of pelvic suppurations. He distinguished in the large group of extra- or intraperitoneal abscesses, the abscesses in pre-formed spaces (pyometra, pyosalpinx) and those not in pre-formed spaces (abscesses in paravaginal, paramitral tissues, in subperitoneal pelvic tissues, and in the connective tissue of the abdominal walls), with intermedial position of ovarian abscess.

The abscesses might be single or multiple, or in the most varied combinations. The cause was always an infection. Amongst these was the gonorrhœal, the puerperal, and, "last not least," the infection of medical assistance (from the sound, curette, intra-uterine injections, caustics, operations on the cervix, and vagina). These abscesses terminated very differently. Inspissation, absorption, and spontaneous cure might take place, or perforation into the neighbouring organs, and spontaneous cure or perforation into the peritoneum with circumscribed or general fatal peritonitis and pyæmia. Occasionally death took place from amyloid disease. The old motto, *ubi pus ubi evacua*, was to be firmly held to, and this was to be carried out wherever the pus was accessible by simple, sparing, conservative methods. Incision came first under consideration. This was before all indicated with solitary uncomplicated pus cavities, whether lying within or without the peritoneum, or whether done from the vagina or abdominal wall. It should not be done through the rectum, as he had observed that healing was difficult.

He made abdominal incision either above or below Poupart's ligament, at one sitting where dulness was complete, at two sittings if intestine apparently intervened. The first incision as for ligature of the iliac artery, pushing up the peritoneum, packing with iodoform gauze, &c. A means of distinguishing abscesses from induration, exudation, and fibroids, indispensable in many cases, was exploratory puncture. It at the same time formed an important preliminary to the incision. When operating from the vagina it was always done at one sitting. Solitary abscesses in the pelvis of whatever kinds were to be treated in this way, even pyosalpinx when the pus was in one cavity.

Considering the good results obtained by simple incision the attempt was justifiable to try it in multiple abscesses (double one cavities, pyosalpinx, &c.). The causes of recurrence might be in fineness of the walls of the abscess, in adhesive fixations preventing the walls of the abscess falling in or otherwise.

For cases in which simple incision would evidently be insufficient as in multilocular pyosalpinx, with or without perforation into the pelvis or abdomen, bladder or multiple perimetric and perisalpingial abscesses, a variety of other procedures had been practised of which he would only mention historically the little promising sacral and parasacral incision.

Here laparotomy was the operation usually practised, with removal of the abscess walls and its contents.

He had treated 141 cases of inflammatory and suppurative tubal disease by laparotomy, with a mortality of 2·8 per cent. This undeniable good result coincided with those of other operators (Chrobak, Schanta, Zweifel, and others).

But, unfortunately, as observation had shown, the permanent results were not equally favourable. Complete cures took place in only from 60 to 80 per cent. (Chrobak, Schanta, Landau.) The reasons for this were threefold :—

1. In the disadvantages of laparotomy itself (abdominal hernia, adhesion of intestine and omentum to wound and to one another, &c.)
2. In recurrences of inflammation and suppuration through impossibility of removing all excitors of inflammation.
3. In the purulent nature of the disease.

Then arose the question, how could these disadvantages be guarded against ?

The first step thereto attended by success was made in France; in the first place by Péau, and after him by Ségond, Doyen, Richelot. The uterus was removed, and excellent results had been reported from this method of treatment. But want of exact pathological data made it difficult to determine the value of such a mutilating operation.

Spurred on by the statements of Péau and Ségond, and instructed by a number of vaginal extirpations of uterus performed since 1881, he had treated since May, 1893, 26 cases by the French vaginal procedure.

He had, however, deviated from this method in two essential points and had extended the limits of the operation as laid down by these authors.

He had never contented himself with removing the uterus and leaving behind the adnexa but had always removed the diseased parts. He had adhered to this principle so firmly that when it was impossible to root out all the disease per vaginam he had also opened the abdomen from above. He had, moreover, operated in this way on women when there was not only a simple double inflammatory disease, but in cases of complicated pelvic abscess. His definition of complicated pelvic abscess was one when, independent of double pyosalpinx or ovarian abscesses, there were present perisalpingial, periphoritic, or multiple isolated intra- or extra-peritoneal abscesses; thus perisalpingitis purulenta, perimetritis purulenta, pyocele uterina, retro-peritoneal suppurations.

Such were cases that could neither be treated by simple incision from the vagina or through the abdominal walls by laparotomy as it would either be impossible or would be too dangerous to carry out the operation.

In all these cases there were multiple collections of thick, yellow, or green stinking, decomposing, or creamy pus. In some cases there was fistulous communication into the bladder or rectum, most of the cases were disabled from long standing disease, and six had been repeatedly treated in other haspitals. In a large number operation had been already performed with temporary success (puncture, incision, resection, laparotomy).

In some cases the attachments to the rectum, and especially the sigmoid flexure and to the bladder, were so firm that in carrying out the principle of removing all diseased parts, the walls of these organs were torn. In two cases of vesical fistula originating in this way, he had operated there and then, once from the vagina and once from the abdomen. In two ruptures of the sigmoid flexure he had performed circular resection.

The whole of the 28 cases were cured by the operation.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, June 8th.

CANCER OPERATION.

Prof. Weinlechner showed a patient who in 1892 came to him with a carcinomatous infiltration which began to discharge the following year. Operation was then resolved on, which left a large defect over the anterior part of the High morian sinus. Later he removed a part from the side of the neck and by ingenious folding brought it over the epidermic surface and restored the defection.

DETERMINING LEUCOCYTES.

Dr. Elzholz gave his experience and the result of his examination of the morphological elements of the blood both in regard to quality and quantity. Erb's method, he said, was far too delicate and unreliable in practice. The apparatus known as Thoma-Zeiss' enumerator was also defective. Where the sheaves were thick the leucocytes escaped diagnosis, although present in abundance. The most rational method of determining with accurate results is either by diluting the blood, when the red blood corpuscles can be destroyed and the white preserved, or by determining by a micro-chemical substance which will attack the leucocytes. The latter method might be conducted with a solution of the following composition.

Two per cent. eosin solution, 7 gramms ;
Glycerine, 45 gramms ;
Aqua distillata, 55 gramms.

The whole to be shaken three or four minutes.

Another mixture of four drops of concentrated solution of gentian to 15 of water and one drop of alcohol, to be shaken for five minutes. The enumeration can then be made by means of Zappert's modified form of Zeiss' chamber. The polynuclear leucocytes will appear strongly coloured, while the eosinophile cells will assume their violet-red characteristic colour, and the other leucocytes the blue tint. A small number of cells in Erhlich's preparation which are never coloured are also left colourless by this test, which seem to be the transitional form of cell. In all his control experiments he found this colouring mixture was free from the usual blemish of destroying any of the leucocytes, and considered it most reliable in the diagnosis of leucocythosis. It had also the advantage of rapidity and accuracy. It has the disadvantage of Erhlich's method in not diagnosing the lymphocytes from the mononuclear transitional form; neither do the specimens come out so prettily as in Erhlich's preparation.

Diphtheria and School Hygiene.

Kolm raised a discussion on the prophylactic treatment and prevention of diphtheria in school children. The law affirms that where one case of diphtheria has appeared that the school shall be disinfected and the relatives of the child held in quarantine for fourteen days; if two cases appear the school must be closed. This he considered an unreliable test of diphtheria, and described his experience of two schools where diphtheria had thus been treated, and found in one class five children, in another eight with a white deposit on the fauces, uvula, isthmus faucium inflamed, and the tonsils greatly enlarged, while the children to all external appearances appeared well and healthy, complaining of nothing. In other cases catarrh was reported, which seemed to him only another name for a modified form of the disease, which included a number of nervous diseases, a dilation of the blood-vessels, with even slight paralysis, which was frequently accompanied with reddening of the mucous membrane and decided disturbance of its function. Concerning the contagious property of the virus, he thought there was no doubt on the subject, and that the principal site of attack in children was the isthmus faucium, which was more exposed by reading and swallowing, which would always remain a *locus minoris resistentiæ*.

It is now forty years since diphtheria appeared in Vienna, and since that time it has fluctuated greatly. Its intensity has varied as epidemics of pest and variola. The course of the disease is not modified by the individuality, but by the intensity of the contagium. It may, therefore, be assumed that diphtheria may be as easily banished as any other pestilence or variola by proper prophylactic methods. He thought the attacks might be divided into four groups, and that children had great exposures to infection by the mouth with lead pencils and pens from infected children, that others suffering from mild attacks infected healthy children in school. He thought the best protective measure would be the subjecting of every child to sprays of potassium permanganate, which was quite practicable with proper care in every school, and proposed that a committee of medical men should be appointed to investigate its propriety.

Dr. Eisenschitz thought that the lecturer's examinations were far too superficial to be placed as reliable data, although many of the red throats must be viewed with ominous danger.

Prof. Paltauf agreed with Eisenschitz, and added that simple spraying with permanganate of potash had no destructive effect on the contagium. In Austria they had more stringent sanitary laws on this subject than many other States. The parents were bound to keep the children at home till the affected members were perfectly well.

Kolm said that fourteen days in Austria was held to be sufficient, while in other countries it was six weeks.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Wiring the Patella.—Mr. Rose operated on a case of transverse fracture of the patella which had occurred ten days previously in a man, æt. 28. Instead of making the usual median vertical incision, he reflected the integument by means of a crescentic incision; this was done for the following reasons:—(1) Because the parts beneath could be more easily exposed; (2) Because the resulting cicatrix is not subsequently in the patient's way when kneeling; (3) Because better drainage can thereby be obtained if necessary. On exposing the seat of fracture, an abundant deposit of lymph was found on the broken surfaces. Mr. Rose then pointed out a condition which he had met with several times before, namely, that the general cavity of the knee-joint was completely shut off by a dense velvety layer of newly-deposited lymph, hence the operation might be said to be in reality extra articular. Two holes were accurately drilled in each broken half, care being taken that the point of the drill emerged on the broken surface at the junction of the articular cartilage and bone, so that the silver wires when passed and tightened up would not show on the articular surface. The patella fragments were thus brought into complete apposition, a few bleeding points were secured by ligature, and the integumental wound closed by a continuous suture. No drainage tube was used in the case, but firm and distributed pressure was considered sufficient.

ST. THOMAS'S HOSPITAL.

Operation for the Complications of Otitis Media.—The patient operated on by Mr. Battle was a boy, æt. 16, admitted with symptoms of great severity, which had commenced about five days before. It appeared that he had suffered from disease of the middle ear, with purulent discharge and partial deafness on the right side for some time. The present illness commenced with pain about the head on the right side, and some sickness. He had also had one or two rigors, and some delirium, whilst the headache had become more intolerable; he suffered from fever, and was becoming very drowsy. On admission, the boy had a dusky face, complained of severe headache, and had a high temperature. Local examination revealed some purulent discharge which came from the middle ear, the presence of a very considerable enlargement of the glands on the right side of the neck, and a general tenderness of the glands, mastoid process, and right occipital region; there was no œdema or redness over the mastoid; slight optic neuritis was present in the right eye, and there were signs of early pneumonia at the left base. Mr. Battle operated at once on arrival at the hospital. He trephined the mastoid process, and opened up the sulcus lateralis; in the former a quantity of thick yellow pus was found, and in the latter a larger amount of thin extremely offensive pus, which was lying in a cavity, the lining of which was shreddy and sloughing. Pressure under the ear caused an increased flow from the extra-dural cavity. These cavities were washed out carefully with perchloride, 1 in 1,000, and the mastoid opening scraped out. Mr. Battle then made an incision in the line of the internal jugular with the intention of tying the vein in the upper part of the neck under the enlarged glands; these were, however, so adherent that they could not be displaced out of the way; the incision was therefore prolonged and the vein secured about the level of the cricoid. The operation at this point was difficult because an inflammatory infiltration along the vessels thickened and bound parts together, so that they were hard to separate and the pulsation of the carotid could scarcely be felt. Two ligatures were passed round the vein, the lower one was tied, the vein was then cut across, and as puncture of the lateral sinus proved it to contain fluid blood, and blood flowed freely from the upper end of the vein, that was closed, but the lateral sinus was not opened, Mr. Battle remarking that he considered it safer to close the vein as there might be a thin layer of clot near the extra-dural abscess, though it was not sufficient to completely block the sinus. A drainage tube was placed in each wound and double cyanide dressings applied. Mr. Battle considered that the patient was suffering from pyæmia in an early stage, and that two of the symptoms were specially unfavourable in considering the prognosis, namely, the duskiness of the face and the signs of pneumonia, but that he could not say when one of these patients suffering from the severer complications of middle ear disease was beyond chance of recovery if surgical help were afforded. He regarded the infiltration in the neck to such an extent as evidence of extension of the suppuration along the vein through the jugular foramen, an opinion confirmed by the increased flow of pus through the opening in the skull on deep pressure under the ear; he said it was not unlikely that an abscess might form in the upper part of the neck, which would require further operation. It is satisfactory to state, however, that no unfavourable symptom has occurred, and that the patient is rapidly convalescing. The medical man, Mr. J. S. A. Wright, who sent the patient to the hospital recommended his removal there some days before, but the patient would not consent.

WEDNESDAY, JUNE 13, 1894.

MEDICAL CONGRESSES AND THEIR CRITICS.

OUR contemporary, *The Times of India*, devotes a long article in its issue of the 7th ult. to the discussion of the forthcoming Indian Medical Congress to be held in Calcutta, as well as to the subject of medical congresses generally. The conclusion arrived at is that international congresses have found more favour with medical men than with engineers, mechanics, lawyers, or clergymen, and the writer proceeds to say that "it is the doctors of Europe who have felt most that they had something to disclose for the benefit of mankind, and with this profession an annual international congress has become a confirmed institution. Eleven of these medical congresses have already been held, and the longer they are held the more they seem to be liked. Each succeeding congress is more largely attended than the one before it, the number of delegates increase, and so do the number of papers and speakers. This increase in the number of delegates and the number of papers may be assumed to be useful to the advance of medicine and its numerous branches. But these congresses are becoming costly businesses. Fêtes and excursions have now become parts of the annual function, and with the increase in the number of delegates there is exhibited an extravagant increase in expenditure on pleasure fêtes and excursions. As very large numbers of medical men take their holidays at the same time, and leave their homes to go long distances to attend the congresses, the question may be asked whether everyone concerned with sickness derives the same benefit from the congress as the doctors. No less than seven hundred of the latter went to the congress at Rome from the United Kingdom. There is, therefore, some reason to suppose that many sick persons were suddenly called upon to change their medical attendant." We quote this passage in full, for the purpose of showing our readers that the subject of medical congresses is beginning to attract the attention of laymen, and to excite adverse criticism. Of course it will be at once seen that the opinions expressed in the quotation we give are not entirely correct. In the first place there is no such thing as an "annual" international congress; nor is it correct to say that "each succeeding congress is more largely attended than the one before it." As a matter of fact the writer has based all his remarks upon the recent meeting at Rome, at which the attendance is reported to have reached 9,000 members. But it is far from likely that any such collection of medical men will again distinguish a meeting of an international medical congress. Obviously the majority of those present were attracted by the place of meeting and the published statements which were made of the facilities provided for members of the congress to visit all the objects of interest in Rome and its neighbourhood. In point of numbers the Roman Congress certainly established a record, but it is certainly wrong to draw any conclusions as to the organisation, management, or prospects of future congresses merely from the incidents which distinguished the Roman meeting. Then, again, so far as the increase of papers offered at these meetings is concerned, it is well known that many medical men place their names down as intending contributors, who purposely fail to carry out their undertaking. The reasons for doing this are best known to those who adopt the practice, but we cannot see that this is any argument against the holding of medical congresses. Our contemporary asks, "What can the medical sciences gain by an assembly of 9,000 with 2 per cent. only of the papers read and adequately discussed?" But it is by no means the case that the scientific value of an International Medical Congress ought to be estimated merely by the number of papers which have been read and discussed at it. On the contrary, it is seldom that a tithe of the scientific work done for such a meeting ever sees the light until the *réunion* has become a matter of history. The great utilitarian feature about a congress is that it stimulates the scientific workers in the profession to bring forward their best work with a view to publication, and without such stimulus quite possibly much that has proved of use to medical science would not have been made available for the profession. We cannot, therefore, agree with our contemporary that it would be a good plan to limit the attendance at these congresses to any particular number; such as, for example, 500 members, or that it would be expedient to make no efforts to promote the success of the forthcoming congress at Calcutta for fear of the meeting becoming unwieldly from overcrowding. Our belief is that both directly as well as indirectly medical congresses are of service both to the profession at large as well as the public, and that, with proper organisation, whatever the attendance is, no difficulties should ever arise.

◆

OLD WORLD SANITATION.

The ancient town of Congleton, in Cheshire, offers a curious object-lesson of the survival of old-world sanitary darkness. It is of historic fame, with a charter of incorporation dating from the time of Charles I., but of late it has fallen on evil times. Its staple industry for generations was the manufacture of silk, a trade which has not only deserted Congleton, but is being rapidly transferred from Great Britain generally to other countries. The townsfolk have not developed any fresh commercial enterprise, so that the prosperity of the place has waned and its revenues dwindled well nigh to starvation point. This straitened condition of income may in part account for the reluctance of the authorities in setting about the much-needed task of sanitary regeneration. Thirty years ago, however, there were plenty of funds available; but for all that the battle of the health reformers was fought and lost. The burning question of that time was the necessity of a system of main drainage, which was ably but unsuccessfully advocated by a prominent citizen. But ratepayers appear to have been alarmed at the cost of providing the necessary works, and the outcome is that Congleton to this day is without any main drainage. The significance of the latter statement will be fully evident to all who are conversant with the practical aspects of modern sanitary administration. A town that has no sewers must of necessity be riddled by cesspools, with all their attendant pollutions of air, water, and soil. The inhabitants of Congleton, even now in its declining days, number about 10,000, and it seems marvellous how they can have lived in such a place without constant and recurrent decimation by filth-begotten epidemics. Nor is that wonder lessened when we learn from the report of Dr. Davidson, the Medical Officer of Health, that the district is distinguished by various other sanitary omissions of the gravest nature. The water supply is reported to be untrustworthy, owing to imperfect filtration, and the authorities have neglected to provide hospital accommodation for the infectious poor. The last item we shall quote in the heavy indictment brought against this town is that practically sanitary inspection does not exist. To quote the words of Dr. Davidson:—"The sanitary inspector is no doubt a capable officer, and quite equal to doing all that is suggested if he had time to do it, but holding also the office of borough surveyor, with the superintendence of several miles of main roads, it is utterly impossible for him to devote to sanitary work a twentieth part of the time it demands." It therefore appears that not only is the public health machinery of Congleton in a lamentably defective condition, but that there is, moreover, no competent official staff to look after matters. A medical officer, one need hardly remark, is powerless to bring about reforms, however urgent, unless he is backed by the authority whom he serves. It is equally obvious that he must depend for information to a great extent on the activity and acumen of his sanitary inspector. There can be no question that in a town of 10,000 inhabitants, especially in one that dates back several hundreds of years, the most active of inspectors would find his hands full if he discharged his duties in anything like a conscientious manner. This point of plurality of posts is constantly cropping up in municipal affairs, and its stern repression in civil life is one of the main principles of modern reformers. The evil is by no means confined to the provinces. To a greater or less extent it may be found all over the kingdom, and in London it certainly exists here and there to an extent that is hardly credible. It is to be hoped, then, that the inhabitants of Congleton will awake from their Rip van Winkle slumber and begin by appointing what is known as a "whole time" inspector as the servant of their Medical Officer of Health. From all we can learn it appears that in the past the main objection to sanitary improvements has been their cost; but that can hardly be allowed to stand in the way of obtaining a proper water supply and drainage system in these times of public health enlightenment. The generally-accepted doctrine nowadays appears to be that money spent in necessary sanitary works is so much capital sunk for the public weal in a sound investment, the interest for which will accrue in the added healthiness and well-being of the inhabitants concerned. Certainly nothing can drain the resources of a district more than the support of a large percentage of disabled persons. We trust that the Congletonians will be induced to ponder over the vital importance of the matter contained in the report of their Medical Officer, and that they will of their own accord undertake to set their house in order. Their town at present is a blot on the sanitary fame of Great Britain, although it is far from being alone in that unenviable position. We may confidently expect that steps will be taken forthwith to remove the reproach contained in the conclusion of Dr. Davidson, that "Under the present system sanitation in Congleton is likely to become a mere pretence."

Notes on Current Topics.

The Pupilage Year of Medical Study.

We have more than once observed upon the fact that credit for a year of medical study can be obtained in England by the production of a piece of paper purporting to testify that the holder is pupil of a registered practitioner. We have known and said that these pieces of paper were commonly a means of evading a first year's work and ante-dating the commencement of medical study. A student cannot receive his diploma unless he can show his name in the Students' Register 45 months (or 57 months in the case of five years' students) previously. But if he can get his name into the Register by this pupilage certificate a year before he really starts medical work, he gets off with 33 months, or 45 months, as the case may be. Our representations on this point were, we imagine, not believed by the bulk of our readers, and were carefully ignored by those who knew their truth, including the General Medical Council. At length a case has cropped up so flagrant that it could not be ignored. Six schoolboys in a public day-school applied for registration as medical students, and were registered accordingly. But, on inquiry, it turned out that these young gentlemen were still engaged in the assimilation of Latin grammar and bread-and-butter, and that the "registered practitioner" who certified them was simply their science master, who happened to have a medical degree. But there is worse to follow. Not only is this sham permitted, but the Chairman of the Education Committee of the Council says that it cannot be legally refused. Nay, more: one of the Medical Licensing Bodies "has recognised this day-school as a teaching institution in which the subjects of physics, chemistry, and biology are taught." Thus it appears on official authority that each of these courses, which must—in Dublin—be fulfilled by a three months' attendance on the instruction of a duly appointed Professor, and by a payment of £3 3s. per course, may in England be had by any schoolboy on a form without payment of a penny, and by virtue of such smatterings as a science master may communicate to children. Here is an illustration of the mental blindness of the Medical Council, which keeps heaping upon the student courses on mental disease, vaccination, dental apprenticeship, &c., but concerns itself not whether these impositions represent real study or are only pieces of pieces of paper and shams.

Mr. Robert Harrison Wilson, M.D. Durh., M.R.C.S., has been placed on the Commission of the Peace for the borough of Gateshead-on-Tyne.

Medical Attendance upon the Rural Poor.

A case which was recently tried at the Cardiff County Court, in which a medical man sued a farm labourer for £10 7s. 6d., the balance of an account for medical attendance, claims some notice from us. The facts were as follows:—The defendant's wife was suffering from erysipelas when the plaintiff was summoned to attend her. But in order to visit her professionally he had to travel a distance of nine miles on each occasion, and for this he charged at the rate of half a crown a mile. The judge, however, said that he did not admit that medical men had any recognised charge under these circumstances; the general belief was that medical men charged according to the position in life of the patient. Further evidence showed that the total amount of the account was £25, of which £15 had been paid. But the defendant informed the Court that in order to pay the latter sum he had been compelled to sell a cow. In the end judgment was given for the defendant with costs. Of course, in reflecting upon this case, it must be conceded that there cannot be many farm labourers in the country who would be in a position to afford £1 2s. 6d. for the visit of a medical man. In the present instance there is no reason for doubting that the fee was earned; but the point is, whether it is incumbent upon a medical man to undertake to attend a patient in rural districts where no reasonable prospect of adequate remuneration can exist. What we mean is, that a farm labourer who lives at a distance of nine miles from any doctor could not be expected to pay remunerative fees for medical attendance, and, therefore, it would be useless to charge them. But matters would not be improved much in this respect, even if such a farm labourer were in receipt of "good" wages, the wages of this class of the community being notoriously based on a low scale. Clearly, then, the difficulty is whether, under these and similar circumstances, the medical practitioner would feel himself justified in refusing his services, or whether, at a loss to himself, he should undertake the treatment of the cases. Quite possibly, however, it is the case that there cannot be many persons, farm labourers or others, in England, who happen to live beyond a reasonable distance of medical assistance. It may, therefore, be concluded that the details brought out in the evidence at the Cardiff County Court were of an exceptional nature.

The Dublin Medical Will Case.

The efforts made by the Governors of Dublin hospitals to invalidate the codicil to the will of Mr. Gervas Taylor sustained an ignominious collapse last week before their case had well begun. Mr. Taylor—who left property valued at £86,000—had, by the codicil, reduced the sums which he bequeathed to these institutions, and left part of the money thus set free—to the extent of £3,000—to his medical attendant, Mr. Ormsby, of the Meath Hospital. The complainants undertook to prove that when the codicil was made Mr. Taylor was imbecile, and that he was unduly influenced by Mr. Ormsby and others. Since his death the air has been full of innuendos which, if they could have been proved against Mr. Ormsby, would have involved his professional ruin. He has had for several months to sit silent while calumnies—for which there was no shadow of ground—passed from mouth to mouth. But when the case was called for trial the first half dozen witnesses completely dissipated the accusations. It was shown that Mr. Taylor gave his own deliberate instructions to his solicitor for the drafting of the codicil; stated reasons for the changes which he made and discussed them in the most intelligent manner, while witnesses of irreproachable character, who had no personal interest in the matter, confirmed the assurance of his testamentary capacity. Moreover, it was shown that the bequest to Mr. Ormsby was fairly and fully earned by personal regard and constant attention in addition to professional attendance for a long series of years, and that the testator felt and expressed many times his obligation to Mr. Ormsby. The counsel for the complainants appear to have been taken totally by surprise by this evidence, for, as soon as they heard it, they consented to the proving of the codicil, and publicly withdrew the aspersions on Mr. Ormsby, and nothing remained of the case but a wrangle about costs. Mr. Ormsby is entitled to the sympathy and congratulations of his brethren. It is a terrible ordeal for a professional man to have to run the gauntlet of spiteful abuse, exaggeration, and obloquy, and our profession participates in the verdict of complete and honourable acquittal which has been recorded.

Modern Phrenology.

The so-called science of phrenology has long since drifted into the shady bye-ways that are haunted by quack professors and charlatans. Its professions and beliefs have never withstood the test of serious examination, and, so far as we know, the world still awaits a convincing demonstration of its fundamental laws. It appears, however, that a British Phrenological Association is in a state of active existence. Quite lately the President of that society, Dr. Renner, delivered an inaugural address, in which he attempted to associate modern physiological advances with the principles first laid down by Gall and Spurzheim. He gave a review of recent cerebral discoveries, such as the localisation of nerve centres and the development of automatic and other functional action. In conclusion, he declared that the scientific phrenologist stood on a basis of natural law, and not on one of mere speculation. With regard to the last assertion we can only say that phrenology has had plenty of time in which to prove its principles, for it has been before the public for at least a century. The report which we have quoted does not say whether Dr. Renner attempted to explain why "bumps" over the motor area have had a significance attached to them by the phrenologists widely different from the motor functions ascribed to them by Ferrier and others. Or why, again, the numerous important centres at or about the base of the brain should have no corresponding external expression. The learned Secretary is reported to have counselled a closer study of the original views of Spurzheim and Gall, whose views were in strict harmony with all that phrenological science had of late brought to light. If the Secretary can prove his proposition he should lose no time in doing so, for he would at once elevate his hobby to the more honourable position of a serious scientific study. During the course of the evening a member made the pertinent remark that there was a science of phrenology as well as an "art" of character reading. One may perhaps assume that the "professor" who dwells in an atmosphere of sawdust and stale tobacco devotes his time and energies exclusively to the "art"—the practical money-winning art—of phrenological exposition, and leaves science to the *savans* of his sect.

The Indian Medical Congress.

The inaugural meeting of the Indian Medical Congress was held in the Medical College Hospital, Calcutta, on the 15th ult., Surgeon-General Harvey in the chair. There was a large attendance, including three women doctors and upwards of three hundred medical men, representing all branches of the profession. In the course of the proceedings the history of the movement was given, the main features of which have already appeared in The Medical Press and Circular. The cost of the tickets of membership of the Congress will be Rs. 10, and may be obtained from either of the joint secretaries in Calcutta, or from the local secretaries in the different parts of the Indian Empire. An Entertainment Committee will arrange for visits to objects of interest in Calcutta and neighbourhood. The Calcutta season, it may be observed, culminates in the Christmas week, and includes two days' racing and the race for the Viceroy's Cup. Notification of the intention of members to read papers at the Congress should reach the secretaries on or about the 1st of November next. So far, everything promises well for the success of the *réunion*, and the enthusiastic manner with which its organisation is being promoted is sufficient proof that the scheme of holding such a Congress has already become popular among the members of the profession in India.

The Control of Hospitals for Infectious Diseases.

An important proposition is under the consideration of the London County Council; it is founded on a report of a joint committee of the Asylums, Industrial Schools, and Public Health Committees appointed to consider the charge of lunatics and the infectious poor. It advocates a re-arrangement of duties among the bodies carrying on central government in London. The passage of the report dealing with infectious diseases runs: "That all central metropolitan powers in regard to public health should be in the hands of a body composed of elected representatives of the ratepayers, and that the London County Council, being the central metropolitan health authority, the powers of the Metropolitan Asylums Board, relating to the accommodation for the infectious sick and the administration of infectious hospitals, cholera, nursing, &c., and of the ambulance service, should be transferred to the Council." Should this recommendation be adopted it will relieve the Metropolitan Asylums Board of a very onerous portion of their present duties, as the care of the lunatic population will then be their chief function.

Iodoform ad Nauseam.

Iodoform is admittedly one of the therapeutical triumphs of the last quarter of a century, along with cocaine and drugs of the antipyrine class. Even its penetrating, persistent, and oftentimes compromising, odour has not prevented its acquiring and retaining a major position in surgical therapeutics. Useful as this remedy may be, whether as germicide or otherwise—for grave doubts have been cast on its antiseptic properties—it is not so indispensable that its use cannot occasionally be dispensed with, at any rate when circumstances are such as to make it exceptionally objectionable. This is the case when the drug is directed to be blown into the ear by out-patients. The powder, strongly charged with iodoform, is, as often as not, blown all over one side of the head, and whole districts are thereby made redolent of the unsavoury compound. When such a patient leads the way, the thoroughfare smells like the out-patient department of a crowded lock hospital, though fortunately not all those who crowd our streets are sufficiently familiar with these institutions to realise the association.

The Irish Poor-law Superannuation Bill.

The Irish Medical Association, the Medical Officers' Parliamentary Representation Association, and the Poor-law Officers' Association, have, within the past week, been making a supreme effort to get this Bill forward in Parliament. They have sent to London, as delegates, Dr. Jacob and Dr. Oulton, for the Irish Medical Association; Dr. T. Donnelly and Dr. Knox Denham for the Representation Association; and Mr. Manning, of Rathdrum, and Mr. Atkinson, of the North Dublin Union, for the Poor-law Officers. The objects which these delegates set before them was, if possible, to eliminate the opposition of individual M.P.'s, so that the Bill might be read a second time and put into Committee without being "blocked." Obviously this is the only method by which progress could be made, for it would be quite useless to ask the Government to give time for the fighting of such a Bill, considering that they have been obliged to appropriate the whole time of the House for their own Bills. The delegates have, therefore, devoted themselves to eliminating individual opposition, a heavy task considering that any one M.P. can by the words "I object," stop peremptorily the progress of the Bill. Especially, the delegates have striven to obtain the imprimatur of the Nationalist party, as a party, and have induced the Committee of that party to give it special consideration. In any case we must hope for the best. If it be found impossible to clear the ground entirely of opposition, at least a great deal will have been done to influence and impress M.P.'s of all shades of politics, and the labour expended will—it is to be hoped—produce the desired result in the future.

Capital Punishment in America.

The new word, "electrocution," which has been coined to describe the execution of criminals in the United States by electricity, is more or less a euphonious one, however, in an etymological sense, it may be at fault. It is worthy of note that this method of execution has not been adopted by all the States in the United Republic. For example, Connecticut has just passed a new Act which requires the execution of the death sentence privately within the State prison before sunrise, and the method of execution in force in the State is, "the ancient, inexpensive, and very certain procedure of hanging," to quote the words of our contemporaries. Doubtless, if the process of "electrocution" could be rendered more certain, and thoroughly proved to be trustworthy, it would come to be generally adopted by civilised nations. Whatever may be said in favour of hanging there is still a definite element of brutality in it, which causes it to be regarded with repulsion by those who, while not objecting to the death penalty, *per se*, are, nevertheless, desirous of seeing it carried out in a humane manner. Perhaps, in time, "execution by electricity" will come to be generally adopted in the place of hanging; but before this can ever be the case, the advocates of the new process will have to show that it can be confidently trusted to do its work without any untoward accidents.

Professor W. T. Gairdner, F.R.S.

We regret to learn that Professor Gairdner, Physician in Ordinary to H.M. the Queen in Scotland, is suffering from a serious affection of his eyes, which will tend to interfere with his professional work, though, it may be hoped, not to any extensive degree. The discovery of the changes which had occurred was made soon after his return from Rome, where he had taken part in the recent International Medical Congress. It will be a great loss both to the University and the Western Infirmary at Glasgow if, in consequence of what has occurred, Dr. Gairdner will be obliged to resign his connections with these two institutions. Dr. Gairdner is well known to be a most accurate clinical observer as well as an excellent teacher. An interesting instance in this connection may be given. Ten or twelve years ago a patient was admitted into his wards in the Royal Infirmary whose appearance at once struck Dr. Gairdner as being distinctly unusual, and careful notes were dictated to the assistant. Quite recently the same patient returned to the Infirmary, and it was then found, by referring to the previous notes in the ward register, that Dr. Gairdner had accurately described a case of acromegaly, a disease which had not at that time come under professional notice.

A Disputed Appointment.

Some few weeks ago we announced the appointment of a new Medical Superintendent to the Joint Counties Lunatic Asylum at Carmarthen, an appointment of which the local press appeared highly to approve. Since, then, however, a curious incident has arisen in connection therewith. At a meeting of the Lampeter

Board of Guardians, last week, a resolution to the following effect was carried: "That in view of the fact that three-fourths of the inmates of the Joint Counties Lunatic Asylum are Welsh-speaking people, this Board highly disapproves of the appointment of a gentleman ignorant of the Welsh language to be chief Medical Superintendent of the Asylum, and calls upon the members of the Visiting Committee to cancel the appointment forthwith or resign their seats, and that a copy of this resolution be sent to the clerk of the Visiting Committee, the clerks of the County Councils of Carmarthenshire and Cardiganshire, and the Commissioners in Lunacy." We cannot see that any good purpose will be served by lodging a protest of this nature after the appointment has been duly made and officially confirmed. Nor can we admit that the objection has any grounds of validity.

The Papain Controversy.

Under this heading a wordy warfare has been going on in some of our pharmaceutical contemporaries as to the digestive powers of papain, but most of the disputants proceeded on the fallacious basis of comparing papain with pepsin. Now pepsin and papain, as has been pointed out, are essentially different ferments, and although they are employed for similar purposes, they do their work under entirely different conditions. It is, therefore, a mistake to seek to gauge their value under any one set of conditions, for conditions which are favourable to the one may be, and, indeed, are sure to be, just as unfavourable to the other. Papain, being a vegetable ferment, is obviously calculated to deal with a different class of albumenoid bodies to those generally met with in the animal system, and we are told, moreover, that it acts to best advantage in an alkaline medium, a medium which practically puts an end to the activity of pepsin, though it does not lose its powers in a neutral or acid medium. Under these circumstances it is claimed for papain that its digestive properties are exercised throughout the whole length of the alimentary tract. The principal thing to remember about papain is that the crude product, the inspissated juice, is apt to prove irritating. The term papain, however, ought properly to be restricted to preparations of the plant juice from which the irritating principles have been carefully eliminated, and such purified products may be administered even to children without the production of any indications of gastro-intestinal irritation. It is doubtful whether papain will oust pepsin from the position which it holds in the therapeutics of gastric indigestion; but there must be many cases in which the wider sphere of digestive activity possessed by papain will lead to its being employed in place of, or as an adjunct to, the animal ferment.

Father Kneipp at the Vatican.

Father Kneipp is a brave *curé de campagne*, hailing, we believe, from a German village, where he has obtained a very widespread reputation by reason of "cures," which he has succeeded in obtaining principally among the class of patients whose cases have resisted treatment at the hands of the faculty. His cure is simple enough. We gather that it consists mainly of a practical application of the injunction to foreswear sack and live cleanly, substituting pure water for sack, plus the application of frictions to the affected parts, and a rigid diet of rye bread. Not long since, considerable emotion was caused among the *entourage* at the Vatican by the rumour that Father Kneipp, this reverend but irregular practitioner, had been summoned to attend His Holiness, at the suggestion of Cardinal Monaco la Valetta. The illustrious patient complained of pains in the abdomen, together with stiffness of one knee. In spite of frictions conscientiously applied by Father Kneipp, the knee did not tend to improve, and the abdominal symptoms were aggravated by the rye bread *régime*, so after a few days the treatment was discontinued. It is stated that at the first consultation the curé took his illustrious patient by the ear, "in order to see whether the flow of blood into that part was free," a *sine quâ non* if success were to follow the treatment! The departure of the worthy curé gave rise to great satisfaction among the cardinals in attendance, for they not unreasonably feared lest so rough a *régime* should prove inimical to the health of one so advanced in years as the Holy Father.

The Association of Fellows of the Royal College of Surgeons, England.

The interest which has recently been shown in the affairs of the Association of Fellows of the Royal College of Surgeons, England, by a large number of Fellows, outside the Association, testifies emphatically to the wide-spread feeling of appreciation which is prevalent of the good work which the Association has done. Indeed, it is impossible to comprehend how any Fellow of the College who has taken the trouble to compare the position of the Fellows now with that which existed ten years ago, can, in his inner consciousness, dispute that to the Association is due the reforms which have been introduced. Of course, it is natural that opposition, more or less of an organised nature, should arise with the object of counteracting the growing influence of the Association. But it is not every Fellow of the College who can hope for an Examinership, or who has prospects of obtaining any remunerative post from the Council; consequently, taking merely a common-sense view of the situation, it is difficult to see how the independent Fellows can fail to support, as hitherto, the candidate, or candidates, nominated by the Association of Fellows.

We are asked to state that a Committee, of which Sir Douglas Galton, K.C.B., F.R.S., is the chairman, and Professor W. H. Corfield, M.A., M.D. (Oxon.), the treasurer, has been formed to further the interests of Great Britain in the Eighth International Congress of Hygiene and Demography, which is to be held in Budapest from the 1st to the 8th of September this year. Any information may be obtained about the Congress from the Hon. Secretary, Dr. Paul F. Moline, 42 Walton Street, Chelsea, S.W.

Mr. Gladstone.

Mr. Gladstone still continues to make good progress. He daily takes drives, and at the present time the ex-Premier, accompanied by his wife, is becoming quite a familiar figure, driving in his carriage, in the neighbourhood of Wimpole Street. There is something very pathetic in the appearance which he presents, with both eyes closely veiled with a black silk handkerchief, and with only the lower part of his features exposed, the pallidness of which at once attracts notice.

The Summer Dinner of the Irish Medical Schools and Graduates' Association will take place at the Midland Hotel, Bradford, on Saturday, June 30th, at 6.30 p.m., the President, Dr. Richard Heath, in the chair. Dinner tickets, &c., may be had by application to Dr. T. Whiteside Hime, 54 Horton Road, Bradford. A fast train leaves King's Cross, G.N.R., at 1.30, arriving at Bradford at 5.34. A Council meeting will take place before the dinner to elect candidates for membership. Those elected at this meeting may attend the dinner and bring guests the same evening.

The Czar of Russia has already shown a great deal of interest in the next International Medical Congress, to be held either at St. Petersburg or Moscow, in 1897, and has contributed fifty thousand roubles towards the expense of the meeting.

The total number of cases inoculated by Pasteur for hydrophobia is fourteen thousand four hundred and thirty, out of which seventy have died of disease. Last year, there were one thousand, six hundred and forty-eight persons so treated, of whom six died.

The body of a married woman who died very suddenly near Aghadowey, co. Antrim, on the 3rd inst., has been exhumed, and the stomach and viscera have been sent to the county officers for analysis. The supposition is that death was due to poisoning.

Surgeon-Major Anthony Hickman Morgan, of the Army Medical Staff, has received the distinction of Companion of the Distinguished Service Order for his services during the recent operations on the West Coast of Africa.

◆

Scotland.

[From our own Correspondents.]

The Late Dr. Malcolm.—The death of Robert Brown Malcolm, M.D., occurred last week in Edinburgh. The deceased, who had attained the ripe age of 86, retired from active practice some years ago. In his day he was a very accomplished and skilful accoucheur. He was a Fellow of the Royal College of Physicians and of the Royal Society of Edinburgh. He was a great believer in exercise, and up to a very short time before his death used every day, whatever the weather, to take a constitutional round Arthur's Seat, a matter of two miles.

Paraffin Wax in Confections.—A test case has been brought against a firm of confectioners in Glasgow for having on Feb. 7th of the present year sold twelve chocolate cigars certified to contain 4 per cent. of paraffin wax extraneous to the chocolate. Sheriff Birnie gave judgment on the 8th inst., dismissing the case. His lordship says that the case was laid on the 6th section of the Food and Drugs Act, which dealt with the supplying of things not in the nature or substance demanded; but when the prosecutor asked for cigars and paid the price of the cheaper cigars, it seemed impossible to say he did not receive what he demanded. Evidence had been led to show that paraffin was injurious to health, and it might be well that parents should know that it was not a food but a mineral extracted from shale; but with injury to health his lordship could not deal under the 6th section.

Convalescent Home for Dumfries.—An unknown donor has generously bought and gifted, through trustees, to the town a large private house at Glencaple, Dumfries, for a Convalescent Home.

Inverness.—A meeting of the Inverness Lunacy Board was held on the 8th inst. to consider the charges made against the medical superintendent. The matter was referred to the General Board of Lunacy.

Protest Against Universities Commissioners.—A meeting was held in the Glasgow Religious Institution on the 6th inst. by the Clan Menzies, and it was decided to protest against the Universities Commissioners disturbing the objects set forth in the will of the testator of the Menzies Bursary.

Out of the 3,750 blind persons in Scotland, 4,142 are under the care of the Mission of the Scottish Outdoor Blind Teachers' Union, which is holding its annual conference in Aberdeen at present.

A jubilant note was sounded last week throughout the Edinburgh Press because the Leith Town Council have at length adopted the Compulsory Notification Act.

The epidemic of small-pox in the Coatbridge and Airdrie districts is still prevalent and slightly on the increase.

Special Articles.

THE ANTWERP EXHIBITION.

[From our Special Reporter.]

I —The Medical and Surgical Section.

As a whole, the International Exhibition at Antwerp, which opened on May 5th, is full of interest, the scientific sections being brought well up to date. I propose to divide my brief report into three parts. In this article I shall deal with the medical, chemical and surgical exhibits; the second will be devoted to dietetics, and the third will treat of sanitary appliances, plans, &c.

In the British section of the Exhibition no attempt has been made to give collective representations, and consequently the scientific side is very far from conveying any adequate idea of the state of knowledge and the skill we possess. As regards medicine and surgery, apart from drugs and antiseptics, nothing is shown. Nor are scientific instrument makers strongly represented. Acoustical instruments of all kinds, suited to different stages of deafness are exhibited by Reiss and Son, of the Strand, London. Optical goods are better represented. A comprehensive show, including clinical thermometers, various necessary instruments, as well as spectacle lenses, is made by Watson and Sons, of High Holborn, London. A remarkable instrument is the microscope for scientific research designed by Dr. Van Heurch, of Antwerp, and made by the London firm. It possesses very high magnifying powers, and is easily adapted to the most awkward conditions for research. Burroughs, Wellcome and Co. have a trophy of their specialities and some novelties in drug preparations, the "tabloid" system being capable of wide application, naturally lends itself well to explorers and medical practitioners in the colonies. An exhibit of melancholy interest is the case carried by Surgeon Parkes on Stanley's last African Expedition, filled with drugs in "tabloid" forms. "Tabloids" of compressed tea are the latest novelty of the above firm. The tea is guaranteed pure, with but a small percentage of tannin, and the "tabloids" dissolve quickly and make a capital brew. They are likely to prove a boon for travellers, in the sick room, and for nurses, as they are easily kept sound, and facilitate brewing. It is a pleasing phase of modern progress to see how largely attention is turned to cleanliness. In this British section there are several antiseptics, also soaps for toilet and medicinal purposes. The antiseptic properties of borax and of boracic acid are interestingly exemplified by the exhibits of the Patent Borax Company, which include "Queen of Antiseptics," borax, sanitary powders and other toilet preparations having a boracic foundation, borax food preservatives, voice and throat crystals, &c. This Californian borax seems to be pure and rich, judging from the tests and analyses. Other antiseptics are shown by the Cyona Company, the preparations having met with scientific, medical and veterinary approval at the Chicago Exhibition.

The Belgian scientific sections are very noticeable on account of the abundant evidence of Government support afforded to scientific research and professional work. Physiology and hygiene are branches of study given prominence in all grades and classes of schools and colleges. The Ecole Professionelle Ménagère has special sections devoted to hygiene and "maternal pedagogy." The idea is to begin with the infant and build up a healthy and strong individual; but the medical men say "first begin by studying surroundings and improve them, so that there may be a chance of individual attention giving good results." Consequently, they are very particular in the drawing up of demographic and pathologic statistics. The Royal Society of Public Medicine of Belgium send an elaborate series of maps on the geographical distribution of diseases, general and seasonal, during certain stated periods, with a geological index. There are further tables giving details as to the description of diseases and mortality for each of the twelve geological zones. The Brussels Medical Society completes this work by a series of graphic and statistical tables on the localisation of diseases and mortality compared with the seasons and various meteorological conditions, though electrical phenomena seem to be entirely overlooked. Dr. Demets contributes a carefully-drawn-up table, giving the graphic curves of short-sight among school children, in combination with distinctive curves demonstrating the good or bad lighting of each school. Observations were made on 3,532 girls and 3,508 boys in average primary schools. Two sight curves are given, one for children under, and another for children over, six years of age; naturally the second shows a much higher curve, but the whole percentages seem to be abnormally high. An interesting feature of the table is the evidence it affords that bad lighting is not necessarily a chief cause of bad sight, for although the high percentage curve is generally found coinciding with the highest pitch of bad illumination, it is not always so, and there are several remarkable instances to the contrary. Probably one determining cause is the bad state of drainage existing in many Belgian towns, the closet arrangements in private houses and public buildings being deplorably defective, and this, combined with want of ventilation, may bring about general weak health or local affections of the eyes, or both. This aspect of the matter will be discussed at a later stage, and for the present it will be sufficient to draw attention to the admirable statistical work of analysis done by the medical men and societies of Belgium. The above tables are supplemented by graphic and statistical accounts of births, deaths, marriages, and density of population.

To return to the educational efforts. The children are taught the elements of physiology and chemistry, and at a later stage there are higher schools, such as the Ecole Professionelle Ménagère. To combat one of the great causes of disease and death among children of the poor—malnutrition—full details are given as to the principles underlying dietetics, and then the lessons are practically applied. In a table dealing with the feeding of infants are the following useful comparative analyses of standard milks: Mother's milk—water 87·09, nitrogenous matter 2·98, fat 3·9, sugar 6·04, salts 0·49; that of the ass—water 90·04, nitrogenous matter 2·65, fat 1·39, sugar 6·25, salt 0·31; cow—water 87·41, nitrogenous matter 3 7, fat 3·66, sugar 4 82, salts 0·70; sheep—water 81·63, nitrogenous matter 5·83, fat 4·86, salts 0·73; goat—water 86·91, nitrogenous substances 4 06, fat 4·09, sugar 4·45, salts 0·86. The hygiene of the baby to childhood is gone into with equal care.

In the Chemistry departments we see a number of patent medicines, several new disinfectants and germicides, and some excellent samples of pure drugs. The Germans seem to have made great advances in this direction. Bandages and dressings are shown in various sections. From Austria, Termohlen and Co. send antiseptic dressings of every description, carbolic acid, iodine, &c., also antiseptic waddings and gauzes. This firm also exhibits catgut for ligatures, silk, and various-sized rubber tubing sterilised and hermetically sealed in sterilised alcohol, special bobbin corks being provided to assist the withdrawal of the article for surgical dressing. Dr. Hertogh, of the Medical Society of Antwerp, contributes a number of instruments specially designed by him in the course of his surgical practice. Among his inventions is an ingenious air-tight metal box for the conveyance of sterilised instruments in alcohol.

Among the many exhibitors of surgical instruments and appliances are quite a number who devote themselves to orthopædic contrivances, malformation and disease of the feet and knees being conspicuously common in Belgium. For surgical dressings we find cardboard sterilised and antiseptic mouldings of arms, legs, &c. To obviate the charge of heaviness and undue heat, moulds are also made in antiseptic coarse gauze on whalebone or metal frames. P. J. T. Firoel-Janssens, of Antwerp, shows some remarkable artificial limbs, eyes, eyebrows, noses, and a movable upper lip. In the Military division are shown an ambulance pharmacy waggon complete, and ingeniously contrived to economise space. There are also ambulance waggons, two- and four-wheeled. These are made strongly with good springs, the top parts being framework covered with coarse brown waterproof canvas. The same canvas is employed for the stretchers. In another section of the

Exhibition examples are given of how photography can be made to assist medicine and surgery. Some very excellent prints are given of abnormal growths and conditions, also of photography as a detective, the negatives of skin prints, &c., being greatly enlarged under magnifying power. It is believed that this practice may help diagnosis, if not the study of the growth and progress of disease. For surgical purposes the camera gives useful negatives, the points of which can be studied at leisure. These prints can be made on paper covered with horizontal and perpendicular lines at equal distances, thus giving a number of small squares, by the means of which very accurate measurements can be taken without unpleasantness to the surgeon or fatigue to the patient. But before such prints could be of any real use, considerable skill in focussing would have to be attained. The tendency to bring mechanism to our aid is very apparent in other directions. There are chairs and beds with most elaborate arrangements, some to be worked by attendants and others by the patients themselves.

VOMITING UNDER ANÆSTHETICS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The causation of vomiting under anæsthetics, and particularly under chloroform, referred to in your last issue of May 23rd, may probably be explained by closely scrutinising the methods employed in inducing and maintaining normal anæsthesia. At present two widely-different methods are employed, viz., *the old method*, in which an uncertain and variable quantity of the anæsthetic is inhaled from an uncontrolled reservoir, to which is added for its dilution an equally uncertain and variable quantity of air, and *the new method*, in which a known quantity of narcotic vapour is inhaled from a controlled reservoir, in small and gradually-increasing doses at each inspiration, evenly diffused for its dilution with an unlimited supply of air.

If we compare the quantity of the anæsthetic used and the symptoms respectively endured by these two methods of administering chloroform in recently recorded cases of normal chloroformisation, the causation of vomiting under anæsthetics is satisfactorily explained.

From an uncontrolled reservoir, recorded by Surgeon-Lieutenant-Colonel Edward Lawrie, *Lancet*, May 19th, 1894.—"A male native, æt. 24, was operated upon for the excision of a bubo. The amount of chloroform required to produce full anæsthesia was five and a half drachms, the time occupied to produce it was seven minutes fifteen seconds. The total amount of chloroform employed was five and a half drachms, and the operation lasted for eleven minutes thirty seconds.

The administration was commenced with one drachm of chloroform, which quantity was renewed at each minute for the following two minutes, and half-drachm doses were added at about a minute's interval until anæsthesia was complete, when no further chloroform was given during the last four minutes fifteen seconds, during which the operation was completed.

Symptoms.—Shouting at first, succeeded by noisy expiration; heavy snoring; alternate irregular breathing and holding breath; breathing more regularly, and vomiting bile on returning to consciousness. The time when food was last taken is not given, but one may suppose that the patient was duly prepared for the administration.

Contrast this with the cases recorded in the *British Medical Journal*, December 16th, 1893, by Dr. Carter, of Weymouth:—

From a Controlled Reservoir of Chloroform.—In all, twenty cases of normal chloroformisation were recorded. In sixteen cases, no sickness or any ill effects followed the administration. In four cases, vomiting occurred, which, however, may not have been due to the effects produced by the chloroform, but may be ascribed to the nature of the operation, viz., a man, æt. 28, castration, the operation lasted one hour, with the consumption of four drachms of chloroform; a female, æt. 26, curetting uterus, time 30 minutes, 2 drachms chloroform used; a female, æt. 36, perinæal operation, time one hour, 3 drachms, 40 minims chloroform used; another female, æt. 22, dividing cervix, the operation lasted fifteen minutes, with the consumption of 1 drachm chloroform. On the other hand, a great number of the cases underwent similar operations, and in the case of a female, æt. 65, hysterectomy was performed, time, 2 hours 35 minutes, with the consumption of 8 drachms 20 minims of chloroform, without the occurrence of vomiting. In all these cases, the patients were duly prepared, and had not taken solid food some time before the operation. The following case shows that, if the stomach is full of food vomiting may be expected. A girl, æt. 14, with an accidental lacerated wound in her arm had chloroform administered to her for the purpose of tying some vessels. She was very anæmic from loss of blood, and her stomach full of food. The operation lasted 35 minutes, with the consumption of two drachms of chloroform. She vomited after the operation, but made a good recovery. As death under an anæsthetic is always the result of an overdose, it may be presumed that untoward results may be due to the same cause. If the administration of chloroform is limited to the smallest quantity capable of inducing and maintaining satisfactory anæsthesia, vomiting under anæsthetics will be an exceptional occurrence. In none of these cases were the alarming symptoms observed as those described by Surgeon-Lieutenant-Colonel E. Lawrie, because no stronger vapour was presented at any stage of the administration that could not be breathed comfortably.

I am, Sir, yours, &c.,

London, May 28th, 1894. Anæsthetist.

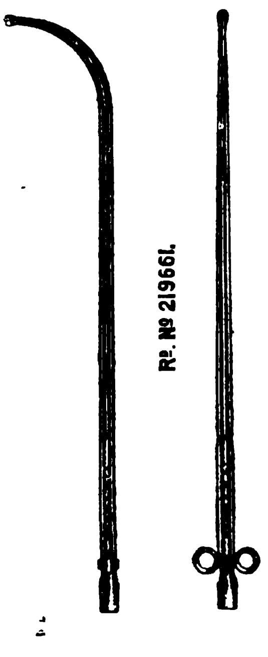
BACKWARD CURRENT URETHRAL INJECTOR.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The enclosed illustration represents an instrument I have been using for some time in the treatment of diseases of the posterior part of the urethra. It is practically an irrigation catheter, ten inches in length, closed at the posterior bulbous extremity, near which it is pierced by ten apertures directed forwards. The apertures are at the bottom of grooves, five in number (two openings being in each groove) which extend the whole length of the instrument except within half an inch of its posterior extremity, and are produced by welding on to the original tube five metal flanges or ribs. The instrument is oiled and passed into the urethra until the exit of urine from its central tube marks its entrance into the bladder. It is then withdrawn to the extent of half an inch, when it is known that the openings in the grooves at the posterior end are in the region of the prostatic urethra. The anterior end of the instrument is then fixed to the tube of an ordinary irrigator, can, or syringe charged with the particular solution to be used, by which means the fluid is forced down the central channel, out at the apertures, and back again along the grooves on the outside of the instrument, and so makes its exit at the meatus. The advantages of this method of injection are that we are enabled by it to act on the whole of the urethra from the neck of the bladder to the meatus, the passage of the fluid into the bladder is prevented by the bulbous ex-



tremity, and dangerous distension of the urethra is prevented, the grooves on the outside of the instrument allowing of the ready exit of the solution.

I have found it most useful in the treatment of gleet dependent upon chronic posterior urethritis. The instrument can be obtained from Messrs. Evans and Wormull, Stamford Street, Blackfriars.

I am, Sir, yours, &c.,
F. W. STOKES, M R.C.S.

"CAUSES OF VOICE FAILURE."

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Will you permit me to reply to a remark in the kind notice with which you have honoured my little brochure "Causes of Voice Failure." You say "we think the advice (*re* diaphragmatic breathing) here embodied would have been even more valuable had the authoress mentioned if from her experience she thought it applied in an equal extent to both sexes, as it is well-known that Nature, or we may perhaps more correctly say the art of dress, causes women to breathe in a far more clavicular manner than men."

I intended the advice on breathing to apply to both sexes, diaphragmatic breathing, with perfect control, being the foundation of all good voice production, whether in speaking or in singing, in men and women alike, while clavicular breathing is a potent factor in voice failure accompanied by throat ailments. From the examination of a large number of cases I find it exceptional for a woman, when dressed, to breathe diaphragmatically, but when the garments are unfastened and a few simple directions followed, Nature's mode of breathing commences to re-assert itself, feebly at first, but vigorously after a little practice. Very many men also breathe clavicularly, to the great detriment of their voices, whether in speaking or in singing. I have noticed, however, that whereas the majority of women *always* breathe clavicularly, comparatively few men adopt this pernicious habit unless when using the voice, which is of course the worst time for them to employ it. As a rule men re-acquire the natural manner of breathing more easily and quickly than women; this may be partly accounted for by their greater freedom from constricting garments. After a few weeks' training of the respiratory muscles the lung capacity frequently exceeds, in women especially, the average given in Hutchinson's tables.

Thanking you, in anticipation, for your courtesy in publishing this letter.

I am, Sir, yours, &c.,
K. BEHNKE.
18 Earl's Court Square, S.W.

ERROR AS TO AUTHORSHIP—AN APOLOGY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am extremely sorry to have made such an error in your columns on May 30th, and I now wish to apologise most sincerely for it to Dr. Leslie Phillips. I would have written to Dr. Phillips himself earlier than I did, had it not been that I thought the mistake in the name was so very apparent, for I was not aware until I received a letter from his solicitors that he resided both in Birmingham and London. Moreover, no time was lost by the editor in pointing out the mistake I had made as to authorship.

Nevertheless, in self-defence I must say that, inasmuch as I do not know Dr. Leslie Phillips, and have no ill-will or malicious feeling against him, I fail to see how he can support a charge of libel against me, and I trust that he will now let the matter drop.

I am, Sir, yours, &c.,
C. R. ILLINGWORTH.
West Kensington, W.
June 8th, 1894.

⁂ [The matter is, as we inferred in our last issue, a mistake as to authorship. The writer having discovered this and made the *amende*, Dr. Phillips will, we hope, accept the apology as readily as it is frankly offered.—ED.]

Medical News.

London and Counties Medical Protection Society, Limited.

A SPECIAL general meeting of the members of this Society will be held at the Frascati Restaurant, Oxford Street, London, on Tuesday, June 19th, 1894, at 4.30 p.m., for the purpose of passing a special resolution, altering the articles of association in the manner recommended by the Council, or in such other way as the general meeting may determine, to change the commencement of the Society's financial year from May 1st to January 1st in each year, and to transact other business of the Society.

Pharmacological Research Fellowship.

IN connection with the recent foundation of a Research Fellowship in Chemical Pharmacology by the Court of the Salters' Company, the Research Committee of the Pharmaceutical Society announces that the selection of the Salters' Company's Research Fellow will take place on July 3 next. Written applications for the Fellowship must be received by the Director of the Research Laboratory, 17 Bloomsbury Square, London, before June 30.

Swansea General Hospital.

AT the monthly meeting of the Committee of the above hospital, held last week, it was announced that someone who wished to be known as "A Friend" had given, through Mrs. Ebenezer Davies, £1,200 for the endowment of a bed to be placed in the institution.

Presentation to a Medical Officer of Health.

AT the last meeting of the Marylebone Vestry, held at the Court House, Marylebone Lane, Dr. Alexander Wynter Blyth, medical officer of health, was presented with a handsome illuminated framed address on vellum on behalf of the vestry, in appreciation of services rendered in connection with the temporary fever hospital opened by the vestry during the period when scarlet fever was so prevalent in the metropolis.

The Meeting of the Medico-Psychological Association at Dublin.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland is being held this week in Dublin: the session was opened by the delivery of a presidential address yesterday (Tuesday) by Dr. Connolly Norman, at the College of Physicians, Kildare Street. Among the members of the Association who have signified their intention to be present and take part in the proceedings are Professor Benedikt, of Vienna; Dr. Jules Morel, Inspector of Asylums in Belgium; Dr. Rene Semelaigne, Secretary to the Medico-Psychological Society of France; Dr. Curwen, President of the American Medico-Psychological Association; Drs. Savage, Hack, Tuke, Mercier, and Percy Smith, of London; Clouston, Elkins, and Batty Tuke, of Edinburgh; Nicholson, of Broadmoor Criminal Asylum; Whitcombe, of Birmingham; Urquhart, of Perth; Rutherford, Crichton Institution, Dumfries; Baker and Price, of York; Lindsay, of Derby; Oscar Woods, of Cork; Ringrose Atkins, of Waterford; Andriezen, of Wakefield; Strahan, of Northampton, &c. Professors Cunningham and Frazer, of Dublin, will also attend and give demonstrations.

Vital Statistics.

THE deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 17·0 per 1,000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year, and were—Birkenhead 21, Birmingham 17, Blackburn 17, Bolton 16, Bradford 16, Brighton 12, Bristol 13, Burnley 18, Cardiff 18, Croydon 12, Derby 13, Dublin 25, Edinburgh 17, Gateshead 17, Glasgow 21, Halifax 18, Huddersfield 17, Hull 14, Leeds 17, Leicester 13, Liverpool 20, London 16, Manchester 19, Newcastle-on-Tyne 16, Norwich 18, Nottingham 19, Oldham 15, Plymouth 14, Portsmouth 14, Preston 13, Salford 21, Sheffield 16, Sunderland 20, Swansea 16, West Ham 16, Wolverhampton 30. The highest annual death-rates were—From measles, 2·2 in Birmingham, 2·5 in Birkenhead, and 2·6 in West Ham; from scarlet fever, 1·8 in Salford.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE PROGRESS OF SURGERY.

TIME A.D. 1870.

Scene: Surgical Ward.

Surgeon: How is Jones doing?

House Surgeon: Extremely well, sir; the wound is suppurating *nicely.*

Surgeon: That's all right.

TIME A.D. 1894.

Scene: The same as above.

Surgeon: How is that amputation of the breast?

House Surgeon: I'm sorry to say, sir, the wound is suppurating.

Surgeon: What! Suppurating!!! *Do you say suppurating!* Well—I'm——(left gesticulating.)

FABLE.—1. Under existing circumstances, we deem it advisable not to publish. It will provoke correspondence of a nature we are desirous of avoiding. 2. The letter on the Hindu question to which you call attention is a powerful indictment against the authorities if the references are to actual facts. It might, however, have a mischievous effect if dealt with in a recognised organ of medical opinion.

MR. BENTHAM.—On absorption of iodoform iodine appears in the urine. Not unfrequently it causes unpleasant results: symptoms resembling meningitis, suffused face, contracted pupils, sterterous breathing—occasionally delirium results. Poisoning by iodoform produces wide-spread fatty degeneration. It possesses no germicidal properties, and is being rapidly discontinued as a surgical dressing. Germs will even grow in powdered iodoform. It does good by absorbing the liquids of the wound, and thus interfering with germ growth. Had it not been so ill-smelling it would long since have been relegated to the obscurity of Koch's cure.

Meetings of Societies, Lectures, &c.

WEDNESDAY, JUNE 13TH.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Lupus Erythematosus.

METROPOLITAN HOSPITAL (Kingsland Road, N.E.).—At 5 p.m., Dr. Tooth: The Anatomy and Pathology of the Spinal Cord. (Post-Graduate Lecture.)

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. William Thorburn: The Surgery of the Spinal Cord and its Appendages.

ROYAL SOCIETY.—Annual Conversazione.

WEST LONDON HOSPITAL (Hammersmith).—At 5 p.m., Dr. Ball: Throat and Nose Cases. (Post-Graduate Course).

THURSDAY, JUNE 14TH.

BRITISH GYNÆCOLOGICAL SOCIETY.—Specimens will be shown by Mr. O'Callaghan, Dr. Eden, and Dr. C. Martin. Mr. J. W. Taylor: Intra-peritoneal Hæmatocele and its Relation to Unruptured Tubal Pregnancy ("Tubal Abortion").

LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Great Ormond Street.—At 3 30 p.m., Dr. Lees: Cases in the Wards National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Gowers: Clinical Cases. Central London Sick Asylum, Cleveland Street, W.—At 5 30 p.m., Dr. Cheadle: Cases in the Wards.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—Living and Card Specimens at 8 p.m.:—Dr. S. Stephenson: A case of Coloboma of the Lens (Double).—Mr. H. Work Dodd: A case of Binocular Polycoria. Papers at 8.30 p.m.:—Dr. James Taylor: Optic Neuritis in its Relation to Cerebral Tumour and Trephining.—Mr. R. C. Ridley: Some Points in the Histology of Trachoma.—Mr. Simeon Snell: (1) Cases of Congenital Serous Cyst of Eyelids associated with Anophthalmos or Microphthalmos; (2) Osteoma of Orbit.—Mr. Spencer Watson: A New Operation for Trichiasis and Distichiasis.—Dr. A. Freeland Fergus: Notes on Peculiar Ophthalmic Conditions occurring in Members of the Same Family.

FRIDAY, JUNE 15TH.

LONDON HOSPITAL MEDICAL COLLEGE.—At 4 p.m., Mr. Jonathan Hutchinson: On Melanotic Sarcoma.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. William Thorburn: The Surgery of the Spinal Cord and its Appendages.

SATURDAY, JUNE 16TH.

LONDON POST-GRADUATE COURSE.—Bethlem Hospital.—At 11 a.m., Dr. Craner: General Paralysis.

MONDAY, JUNE 18TH.

ROYAL COLLEGE OF SURGEONS, ENGLAND.—At 5 p.m., Prof. Pick: Diseases of the Ends of Long Bones in Children.

ST. JOHN'S HOSPITAL FOR SKIN DISEASES (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Tuberculosis of the Skin.

Vacancies.

Coventry and Warwickshire Hospital.—House Surgeon and Assistant House Surgeon. House Surgeon's salary £100 per annum, and Assistant £15 per annum. Applications and testimonials to the Secretary on or before June 18th.

District Infirmary, Ashton-under-Lyne.—House Surgeon. Salary £90 per annum, with board and lodging. Applications and testimonials to the Hon. Sec. by 19th June.

East Riding Lunatic Asylum, Beverley.—Assistant Medical Officer (unmarried). Salary £100 per annum, with board, lodging, and washing. Applications and testimonials to the Clerk to the Visiting Committee by 19th June.

Essex County Lunatic Asylum, Brentwood.—Third Assistant Medical Officer and Pathologist. Salary £120 per annum, with board, lodging, and washing. Applications and testimonials to the Medical Superintendent by 20th June.

Newport and Monmouthshire Infirmary, Newport, Mon.—House Surgeon. Salary £100 per annum, with board and residence. Applications and testimonials to the Secretary by 23rd June.

Royal London Ophthalmic Hospital, Moorfields.—Curator of Museum. Salary £120 per annum. Applications and testimonials to the Secretary by 30th June.

Wolverhampton and Staffordshire General Hospital, Wolverhampton.—Resident Assistant. Board, lodging, and washing provided. Applications and testimonials to the Chairman of the Medical Committee by 25th June.

Appointments

BLACK, B. S., M.B., C.M., D.P.H.Aberd., Medical Officer, Government Bacteriological Department of Medical Science, Cape Colony.

BRYETT, L. T. F., M.B., L.R.C.P.Lond., D.P.H., M.R.C.S., Medical Officer of Health for the Parish of Shoreditch.

CAMPBELL, P., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health for the Pontypool Rural Sanitary District.

COLVILLE, J., M.B., B.S.Irel., Medical Officer to the Belfast Royal Hospital.

JOSEPH, J. J., L.R.C.P., L.R.C.S.Irel., Medical Officer for the No. 2 Sanitary District of the Parish of Battersea.

KIRK, T. S., M.B., B.S.Irel., House Physician to the Belfast Royal Hospital.

MITCHELL, T., M.D., C.M.Glasg., Medical Officer of Health for Llandilo, Talybont.

MORRIS S. G., M.B., C.M.Ed., Medical Officer for the Cwmtwrch and Cwmllynfell Sanitary Districts of the Swansea Union.

POWELL, L., L.R.C.P.Edin., L.M., M.R.C.S., Medical Officer for the No. 2 Sanitary District of the Shepton Mallet Union.

ROBERTSON, J., M.D., B.Sc.Edin., Medical Officer of Health for the Borough of St. Helens.

RUDD, W. A., M.D.Durh., L.R.C.P., M.R.C.S., Assistant Medical Officer to the Infirmary of St. Mary Abbotts, Kensington.

STANWELL, ST. J., M.B., C.M.Edin., M.R.C.S.Eng., House Surgeon to the Stamford and Rutland General Infirmary.

TAYLOR, D. M., M.B., M.S.Glasg., Medical Officer for the Bromley Workhouse of the Stepney Union.

TOLLER, C. W. E., M.D.Durh., L.R.C.P., M.R.C.S., Medical Officer for the Ilfracombe Sanitary District of the Barnstaple Union.

TOOGOOD, F. S., M.D.Lond., M.R.C.S., Medical Officer to the Lewisham Infirmary.

WALKER, W. W., B.A., M.B., B.C.Cantab., Junior House Surgeon to the Great Northern Central Hospital.

Births.

BELL.—June 3rd, at Upgate, Louth, the wife of Charles W. J. Bell M.R.C.S.Eng., of a daughter.

BOWKER.—June 8th, at Cwmbran House, Newport, the wife of C. Stanser Bowker, L.R.C.P., of a daughter.

GROOME.—June 1st, at New Cross Road, S.E., the wife of Walter Groome, M.B., M.S., of a daughter.

KEY.—June 2nd, at Wilton Place, Belgrave Square, S.W., the wife of A. Cooper Key, M.D., M.R.C.P., L.S.A., of a daughter.

WALLIS.—June 5th, at East Grinstead, the wife of P. E. Wallis, L.R.C.P., M.R.C.S., of a son.

WREFORD.—June 2nd, at Clapham Road, S.W., the wife of S. Wreford, M.R.C.S., of a daughter.

Marriages.

BURT - HARROP.—June 7th, at All Saints' Church, Kensington, Wm. Chas. Burt, M.R.C.S., L.R.C.P., of Torrington, to Edith Constance, youngest daughter of the late T. C. Harrop, of Liverpool.

LUMLEY—BALL.—June 2nd, at St. Augustine's, Honor Oak, Frederick Davidson Lumley, Surgeon R.N., to Pattie Codrington, younger daughter of the late Staff Commander Edward Codrington Ball, R.N., K.L.H.

REDFERN—HENRY.—June 4th, at St Stephen's, South Kensington, John Joseph Redfern, M.A., M.D., of Croydon, eldest son of Professor Redfern, M.D.Lond., F.R.C.S., of Belfast, to Eva Maud, daughter of the late Rev. P. Shuldam Henry, D.D., President of Queen's College, Belfast.

REYNOLDS—HALL.—June 6th, at St. James's Church, Brighton, Graham Hay Reynolds, M.B., C.M., of Frognal, Hampstead, to Herculena Maud Millicent (Mag), younger daughter of Major Macdonald Hall, of Brighton, late 1st Royal Dragoons and 62nd Regiments

SIMPSON - STOTT.—June 5th, at St. Pancras Church, John Simpson, B.A., M.D., Highgate Road, London, to Mary Helen, daughter of Thomas S. Stott, M.R.C.S.Eng., Highgate Road, N.W.

Deaths.

GRAHAM.—June 1st, at Barnes, suddenly, Brigade-Surgeon Henry William Graham, India Medical Service (retired), aged 67.

JOLLY.—June 9th, at Bournemouth, Robert Jolly, M.D., F.R.C.S., late of Birmingham.

MALCOLM.—June 5th, at Rosebery Crescent, Edinburgh, Robert Bowes Malcolm, M.D., F.R.C.P.E., and F.R.S.E., aged 86.

WILL.—June 1st, suddenly, at Rubislaw Terrace, Aberdeen, James Will, M.D., J.P., of Woodside.

Vienna Clinical Lectures.

NITRITES IN URINE.

By PROFESSOR MAX, AND ADOLF JOLLES,
Of the Chemico-Microscopic Laboratory, Vienna.

[REPORTED BY OUR OWN CORRESPONDENT.]

SINCE the interest excited by Dr. Latzko in cases of osteo-malacia here, we have further investigated other cases and examined the tests supplied in determining the various constituents of the urine. With this object in view we had also to select cases of osteo-malacia, under varying conditions so that special applications might be carefully examined and fallacies eliminated. Having obtained an undoubted case of this disease we carefully examined the urine day by day for four weeks, with special attention directed towards the nitrites which recently has been assumed to be one of the morbid changes in osteo-malacia. We have found however, and incontestably proved, that this morbid condition is not constant in the urine of all osteo-malacia conditions; we admit that it is sometimes present and sometimes intermittent, one day it may be absent, the next present, or it may be two or three days absent, and a trace of the nitrite found on the fourth or fifth day.

The presence of nitrites in urine has been established by Schönbein to exist in urine after decomposition, but the condition under which it has appeared has not been clearly set out, even this condition of flocculent decomposition of urine has not always been proved to possess nitrites any more than the fresh urine, although Schönbein appears to have met with it frequently and presumed that it was always present in certain conditions of decomposition. His presumption was that the fermentative changes in the nitrates present in the urine were reduced and nitrites formed.

Rhömann has confirmed the results of Schönbein, but has added to this information that nitrites are only present in decomposing urine when nitrates are found in the fresh urine, and that nitrites are not formed through the oxidation of the nitrite of ammonia as was earlier assumed. In consonance with Schönbein and Rhömann I have met with nitrites in cloudy urine which had been acid from the beginning, and which had stood exposed to the air for some time, but immediately the urine became alkaline the nitrites disappeared. This condition I have followed with much interest in different forms of urine, but as soon as the nitrites disappear the urine will become alkaline, or the same state produced by alkalising urine. There are also conditions of urine where nitrates are in abundance where it may stand until the cloudy state of the urine is produced and not a single trace of nitrites to be found in the whole history of the decomposing change. We must therefore conclude that the nitrites are not formed by this change taken by itself, that it is not the cloudy condition of putrefaction that produces the nitrites, nor the reduction of nitrates into nitrites. We must look elsewhere for the potent factors in this production which seem too enigmatical at the present time. I am quite prepared to accept it as an important diagnostic sign in the clinical investigation of disease, but whether it be osteo-malacia, or another morbid condition that is the proximate origin I cannot venture to assume.

The tests for nitrites vary and some may be said to be inapplicable for urine. The most sensitive of these is the reaction with dilute sulphuric acid and iodide of potassium. This is, for water, perhaps quite reliable, but for urine it loses the so-called sensitive reaction owing to a number of ingredients, both in normal and pathological urine that take up the iodine and destroy the test. Among these may be mentioned uric acid, the colouring matter in urea as urobilin, the aromatic products of decomposition, such as phenol, which are usually present in the normal urine. In pathological conditions the products of the gall-duct, such as bilirubin, which is oxidised to biliverdin or choleic acid, albumen and blood all tending to mislead by taking part in the absorption of the iodine.

When we consider these difficulties in the iodine reaction where there are only traces of nitrites present, it is scarcely possible to be so accurate as might be wished, but where no alteration of colour takes place within a certain period we are inclined to decide in the absence of nitrites, but the smallest quantity detected is very variable, especially when depending upon the normal or abnormal condition of the urine as pathological ingredients enter into our calculations. The following condition may be cited as a fair example of the sensitiveness expected by such a test.

Specific gravity at 15 Cent.		1·024.	
Acidity . .		acid.	
Urea . .		25·78	per thousand.

In this analysis the presence of nitrites was very small with the zinc iodide and starch solution, but when tested under gravimetric analysis it gave 0·0015 gr. N_2O_3, or about 10 ctms. in the urine under investigation. Considering the importance of nitrites when found in small quantities in the blood it is necessary to revert to more reliable investigations when suspicion arises and when anxious to determine the quantity of nitrites present. Several other tests are commendable for their accuracy, but the most reliable seems to be sulph-anilic acid and α-Naphtylaminum-sulphuricum. The mode of application in urine is similar to that in water given by the Society of German Chemists, although it is better to watch the changes in the urine by the use of turmeric, or a species of yam. With this object 120 ccm. of the urine is taken and warmed in an Erlenmayer flask to 40°, about half a teaspoonful of vegetable charcoal is added and shaken well and afterwards filtered. With good yam the first filtrate, if the urine be not too concentrated, will be perfectly clear for observing the change of colour. It must be evident to all that extreme care be taken to eliminate all nitrites from the clarifying agent, or fallacies will be sure to arise. The *modus operandi* is conducted with a glass-stoppered cylinder holding a little over 100 ctm. 100 ctm. of the decolorised urine is placed in this cylinder, to which is added 1 ctm. of a colourless solution of sulpho-anilic acid with 1 ctm. of dilute sulphuric acid (1 : 10); the stopper is now placed in the cylinder and the mixture allowed to stand for two or three minutes, when a colourless solution of sulphuric acid—α-Naphtylamin—is added and the stopper replaced. If a single trace of nitrites be present a red or a rose colour will appear within thirty minutes after the last addition. A few examples of the delicacy of this test may be cited from our register.

Test 1.—100 ctm. of urine clarified as above contained 0·000128 gram, N_2O_3. This urine had sulphuric acid added to acidify the urine, 1 ctm. of sulph-anilic acid added, and after several minutes 1 ctm. of the α-Naphtylamin solution, the stopper replaced and left to stand a short time, when a deep rose colour appears.

Test 2.—100 ctm' were treated in the same manner, with the following result: 0·000064 gram, N_2O_3. This also gave a rose colour.

Test 3.—100 ctm. treated as above gave 0·000032 gram, N_2O_3, which also had a slight rose-colour reaction, which did not appear till the solution had stood for twenty-five minutes.

Another very sensitive test for nitrites in urine is that represented by Schäffer, and recently improved by Deventer, but is more applicable for qualitative testing in the presence of nitrates, which gives a peculiar distinct reaction in water. This test as performed by Schäffer is accomplished with a solution of potassium nitrite, a few drops of ferrocyanide of potassium, and a little acetic acid, which produces an intense yellow colour. According to Deventer, the following reaction takes place:

$$2K_4FeCy_6 + 2HNO_2 + 2CH_3COOH = K_6Fe_2Cy_{12} + 2CH_3COOK + 2NO + 2H_2O.$$

We have frequently used this test in our laboratory work, and find the reaction perfectly distinct and accurate when nitrites are present in the urine. The most practical way of conducting the test, in our opinion, is to take about 10 ctm. of the urine which has been decolorised by animal charcoal, and of this quantity, 3 or 4 ctm. are placed in a test tube with an equal volume of dilute acetic acid (1 : 10) to which may be added two, or at most, three drops of a dilute solution (1 : 20) of ferro-cyanide of potassium. In the presence of nitrites this will strike the characteristic yellow colour which can be easily recognised if 0·000045 gram of N_2O_3 be present in 100 ctm. of normal urine. If the quantity be so small that doubt is entertained of the change of colour, it is wise to take an equal quantity of normal urine as a comparison in colour when the slighest change produced by the test can be easily observed. According to Deventer's hypothesis of Schäffer's reaction, one molecule of ferrocyanide of potassium is equal to one molecule of nitrous acid which is observed in the form of nitrous oxide. From this change of constituents, Deventer attempts to formulate a quantitative analysis, and by the aid of the eudiometer measures, the nitrous oxide from the liberation by ferrocyanide and acetic acid. He has obtained favourable results, but our own experience is not so satisfactory. With the object of testing its efficacy, we used a nitrite potassium solution, the quantity of N_2O_3 being known by analysis. One cubic centimetre of this KNO_2 solution = 0·0154 gram N_2O_3. The result of our analysis may be here briefly reviewed. Having obtained a solution of known quantity of N_2O_3, we took 4 ctm. of the solution placed it in a eudiometer containing 25 ctm., and after Deventer's method used a ferrocyanide of potassium acetic acid solution to decompose after which the nitrous oxide was measured. Four ctm. of NNO_2 contained 0·0616 gram N_2O_3 according to the first test, 0·0184 gram was obtained. The second experiment with the same urine and solution gave 0·0306 gram. Notwithstanding these anomalous results in urine, the test seems to be of value when used in water, but in urine it cannot be relied upon.

When quantitative analyses of nitrites are to be taken, the most reliable in practice appears to be the colorimetric method pursued by Trommsdorff, which is nothing more or less than a modification of the zinc iodide and starch solution with sulphuric acid. It is a comparative one, having a solution of known strength, it is treated in the same manner with distilled water as an equal quantity of the urine. We have shown above that many fallacies will arise if the time in examination be delayed, but to obviate this the urine may be decolorised and the analysis conducted speedily before the different ingredients of the urine begin to act on the iodide. Another important point in the volumetric analysis is how many cubic centimetres of the iodide of zinc and starch solution is necessary for producing the blue coloration. The quantity is not constant even in water, and, therefore, for urine must be still more variable. The quantity of sulphuric acid to be added is from 2 to 3 or 4 to 5 cubic centimetres in urine, but, as already stated, many factors have to be observed in order to obviate error.

In order to make myself clear to my hearers, I shall briefly relate the points I desire to be observed in my lecture:—

(*a*) Nitrites are sometimes produced in acid fermentation when the urine is cloudy.

(*b*) We are then unable to say why nitrites are not always present in acid fermentation, even when large quantities of nitrates are present.

(*c*) The tests for nitrates hitherto applied in urine testing with dilute sulphuric acid, iodide of potassium and starch are not sufficiently sensitive or reliable without modification because the normal as well as the pathological urine contain elements that greedily absorb the iodide and render the test useless when small quantities or traces of nitrites are present.

(*d*) The most reliable quantitative test for the presence of nitrites in urine is that of sulphanilic acid, sulphuric acid with α-Naphtylamin which will detect the presence of 0·000032 gram N_2O_3 in every 100 ctm. of urine.

(*e*) The quantitative test of nitrites most in use is the so-called "Schäffer reactions," consisting of ferrocyanide of potassium and acetic acid. Its delicacy reaches 0·000045 gram of N_2O_3 for every 100 ctm. of urine. The quantitative test for urine derived from this by Deventer in his reports to the German Chemical Society are not to be recommended.

(*f*) The most practical quantitative estimation of nitrites in urine at the present time is the colorimetric measure adopted by Trommsdorff, which is only a modification of the zinc iodide, sulphuric acid, and starch solution.

The exact net profit from the "Kosmos" Bazaar, in aid of the City of Dublin Hospital, last year, was £12,005 14s. 5d.,—a splendid reward for the enterprise and labours of its managers. Unhappily, the works of enlargement and decoration, for which the sum was collected, are, and have been for about a year, totally suspended, and the hospital is completely disjointed thereby. We believe that the contractor became bankrupt, and from that day to this the business is in the hands of the lawyers, where it seems likely to stay.

Dr. and Mrs. MacVean, on the occasion of their marriage last week, presented a cheque for £1,000 to the Lancaster Infirmary for the purpose of endowing a bed in the institution.

ON THE TREATMENT OF CERTAIN FORMS OF ADVANCED CANCER OF THE UTERUS. (a)

By FRED. BOWREMAN JESSETT, F.R.C.S.,
Surgeon to the Cancer Hospital, Brompton.

In the compass of this paper I wish it to be understood that I intend to confine my remarks to the treatment of those forms of cancer of the uterus that, on account of the extent of the disease, are totally unsuitable for any form of operative interference, by which I mean vaginal hysterectomy or supra-vaginal amputation of the cervix.

The treatment of these advanced cases of the disease is a subject which has occupied the attention of both physicians and surgeons from time immemorial, and although many forms of treatment have been suggested, no permanent benefit has been obtained, and the poor suffering women who are the victims of this terrible disease have been allowed to perish unrelieved.

Cancer of the uterus, and I use the term cancer here in its broadest sense, including all forms of malignant disease of the organ, has occupied my attention now for some years, and I have given every form of treatment that has been suggested by different surgeons my earnest attention, and with but few exceptions have tried them all, and have been doomed to disappointment.

I have examined the uteri of women who have died in the hospital with a view of ascertaining the cause of death in these cases, and found that a large number died from uræmic poisoning caused by the ureters being obstructed by and involved in the disease, others died from secondary growths, and some died apparently from septic mischief and exhaustion. I was much struck, however, by the limited extent of the disease in the body of the uterus. In many cases in which clinically it was supposed the whole organ was infiltrated it was found that the disease was limited to the external os and neck of the uterus, but that it had extended laterally into the cellular tissue around the neck implicating the ureters, or had extended to the vaginal wall, in many advanced cases invading the bladder in front or the rectum behind.

I therefore came to the conclusion that for practical purposes we might divide these diseases into three divisions.

1st. Those in which the disease was limited to the uterus, this organ being movable and readily drawn down to the vulva.

2nd. Those cases in which the disease had extended beyond the neck of the uterus into the surrounding cellular tissue, thus more or less fixing the uterus in this situation and perhaps the roof of the vagina being slightly involved.

3rd. Those cases in which the disease extended beyond the above limits, invading the vagina and possibly the bladder or rectum, or indeed both these organs.

It is to the treatment of the two latter forms of the disease to which I wish to allude to-night, and it will be well to dispose of those cases included in the third division first.

When the disease has extended to the vaginal walls, implicating the bladder and rectum, I fear nothing but purely palliative measures can be adopted. Our aim must be to make these poor women as comfortable as possible by relieving their pain and keeping the parts as clean and sweet as we can. To accomplish the first object there is nothing which answers so well as morphia and belladonna suppositories introduced several times a day if necessary. I have found relief given in many of these cases by, in the first place, syringing the vagina thoroughly well out with a solution of iodine and water, and here let me recommend this being done through a speculum. I have specula of different lengths, so that if the vagina is much involved I can introduce a short one, such as the one I now pass round, for in all these cases I think it is more important to get as good a view as possible of the diseased parts. Having syringed the parts as thoroughly as possible, I proceed with dry tampons of cotton wool to wipe the parts well, removing as much as possible of the sloughy *débris* which is sure to be present, and finally I apply a solution of chromic acid (ʒij to ℥j) to all the diseased surfaces, being careful not to allow this solution to run on to the healthy tissues. These are protected by applying a saturated solution of carbonate of soda. Finally a long strip of gauze is introduced and a morphia suppository placed into the rectum.

The vagina is kept syringed out with some antiseptic solution some three times a day. In a few days a quantity of sloughy material will come away, and the discharge be very much less offensive, and the pain will be relieved in every case in a most marked degree. The patient improves in general health and the appetite returns. For after-treatment I adopt the plan of inserting a small ball of gauze filled with iodoform or iodol, and a strip of iodoform gauze attached to it. This has the effect of keeping the parts wonderfully clean. With respect to medicinal treatment, I think our great aim must be directed to giving tonics, keeping the bowels regularly opened, and improving the general tone of the patient as much as possible, and ordered the tabloids of chian turpentine and ichthyol.

In this form of the disease, then, we can never hope to eradicate the disease, but we can I am sure prolong life and relieve suffering.

In those cases included under the second division, however, there is a much brighter outlook, and it is in these cases that we can hope not only to give relief, but to remove the diseased parts almost as surely and as effectually as we do in those cases which are suitable for complete or partial extirpation.

It must be borne in mind that the post-mortem examination of a number of cases showed that the disease was limited to the cervix and os. In other cases the body was implicated, but very rarely to such an extent as the cervix, thus pointing to the supposition that the disease usually commenced in the cervical canal and then extended outwards to the cellular tissue beyond. It must further be borne in mind that only in some of the very advanced cases did the patient suffer from secondary growths, although it is true that there were quite a number who had their lumbar and sacral glands infiltrated with the disease, but in many of these cases the glands did not appear as if they had long been affected. We may, therefore, I think, in this class of disease look upon it as a purely local affection, and we may hope if we can remove the growth that our patients may recover, and possibly be radically cured.

The plan that commended itself most to my mind was that practised by Dr. Marion Sims; the thorough clearing out of the advanced disease, however, appeared to me to be of paramount importance. The curettes which were adopted by this surgeon and by others did not commend themselves to me, in fact, I had seen disaster follow their use. I have seen on more than one occasion the curette passed completely through the uterine wall into the peritoneal cavity; moreover, after the uterus has been apparently thoroughly curetted, on examining the surface it has been rough and uneven, with ridges here and there, in fact, these curettes were in my opinion ill-adapted to the purpose. I next turned my attention to Bell's dredgers, but found these did not fulfil all I wished, as they were too pliable, and their calibre was too small. The idea then occurred to me, if

---

(a) Read before the West London Medico-Chirurgical Society, April 6th, 1894.

I could have an instrument constructed somewhat after the principle of Bell's dredger, in which I could increase in size the cutting blades by means of a screw in the handle, and furnished with watch-spring knives so shaped as to enable me to scrape out the contents of the uterus by simple rotation, I should have made a considerable advance, and should be able to accomplish all I required. Such an instrument has been made for me by Messrs. Maw, Son, and Thompson, and, as you will see, is worked by means of a screw at the end of the handle. By means of this screw the blades, which when first introduced lie flat on the central rod, are made gradually to expand until they represent an area of about one and a half inches in diameter. Here then I was furnished with an instrument by means of which I was enabled to remove the whole contents of the uterus with comparative ease, and as the blades are not too sharp, no mischief can be done with them, and very little bleeding follows its use. By using this instrument a perfectly smooth even surface is left, and this is of the greatest importance, as if the surface is uneven the application of the caustic is rendered uncertain and unequal, as in those parts which are elevated it would naturally penetrate very much less deeply than in the depressions.

The next question which arose was the form of caustic and the best method of applying it, and here I followed in the steps of Dr. Marion Sims in using absorbent wool soaked in a solution of chloride of zinc. There is, however, a great difficulty in getting this wool prepared strong enough, as if a saturated solution is used the wool becomes unevenly saturated, and it is knobby and hard. Mr. Stevens, chemist, has taken a great deal of trouble in the preparation of this wool, and he tells me the strongest solution he can use is chlorid. zinci ʒvj to water ℥j. After saturation the wool is carefully dried and kept in a firmly stoppered bottle ready for use. In very bad cases, however, I have been in the habit of having a paste of chloride of zinc prepared at the time of operation, and soaking the wool in the paste, and getting it as dry as possible by squeezing it out in a piece of gauze, and then packing the cavity which has been cleared out with it. Great care has to be exercised in packing to prevent the caustic from running over the healthy vaginal walls.

Method of Applying the Dredger and Caustic.—The patient being thoroughly anæsthetised, is placed in the lithotomy position with Clover's crutch. The vagina is then thoroughly irrigated with carbolised water, a Sims' speculum being introduced. By means of stick sponges the vagina is then dried. The dredger closed is now passed into the diseased canal and rotated from left to right. At the same time the blades are opened by means of the screw in the handle. The dredger very shortly becomes full of broken down diseased tissue. This is readily removed by rinsing the blades in a basin of warm carbolised water. It is then reintroduced and the blades slowly opened, the instrument being removed from time to time and rinsed until it is found that the parts from whence the disease has been removed presents a perfectly smooth surface. There is usually but little bleeding, nothing more in fact than a general oozing. This is readily arrested by having some water as hot as possible and by means of stick sponges applying this to the cavity; when this is found to be fairly dry the process of packing commences. Should there be much bleeding it will be advisable to check this either by touching with Paquelin's cautery, or plugging with gauze firmly, or applying perchloride of iron lint. In this case the packing with the zinc wool must be postponed until the next day, when it can readily be done in the ward.

Packing.—This is best done by having very small pieces of the wool and packing these in with uterine forceps, an assistant steadying the uterus by pressure above the pubes. It is astonishing what a quantity of wool can be packed in these cavities. When the cavity is quite firmly filled I place over the mouth a ring pessary with rubber diaphragm. The object of this is to prevent the action of the chloride of zinc at the orifice from being neutralised. The vagina is now plugged with tampons of wool soaked in a saturated solution of carbonate of soda. I find it a good plan to introduce one tampon thoroughly soaked and allow it to remain in for a few minutes, and then remove it so as to neutralise any of the caustic which may have leaked on to the vagina wall. Three or four plugs soaked are now passed into the vagina; and here again you will find it a great convenience if you have them tied together in the form of a kite's tail, as it saves so much trouble when removing them. The patient is now returned to bed

The next day the carbonate of soda tampons may be removed and fresh ones introduced, or they may remain in for some few days. Should there be no tenderness or rise in temperature the chloride of zinc packing need not be removed for four or five days; this is most easily extracted by means of Marion Sims' screw, which consists of a long straight steel rod with a very fine double screw, like a very small corkscrew at the top. After the packing is removed the vagina and cavity should be well syringed out with some antiseptic solution. I prefer weak iodine and water. A piece of iodoform should be packed into the cavity. This should be removed night and morning and the part syringed on each occasion. In syringing the vagina I prefer using a full-sized Ferguson speculum, as it is much easier to syringe out any sloughs or *débris* that may be detached.

At the end of from 7 to 10 days the slough created by the caustic will become detached, and can readily be removed, by means of uterine forceps. The slough should always be allowed to become quite loose before being removed, or troublesome hæmorrhage may follow. A healthy, clean, granulating surface usually is left. In some cases it may be necessary to repack the cavity if the disease does not appear to be removed. Should portions of the surface appear roughened with nodules present here and there, I have caused these to be removed by injecting a few drops of solution of chromic acid, ʒj—℥j, directly into the growth by means of a long hypodermic syringe. This has a very marked effect, causing the nodule to become hard, and this after another week or ten days detaches and can readily be removed.

With regard to medicinal treatment, I have been in the habit of giving small doses of bromide of arsenic, with, I think, in some cases, good effect. Chian turpentine also appears in some cases to tend to cleanse the parts. I have had some tabloids prepared for me by Burroughs and Wellcome, composed, some of chian turpentine, chloride of gold and sulphur, others of turpentine, pyo-tannin, and ichthyol. These tabloids have proved most successful in these cases.

I have now treated a number of cases by the method I have described, in many with very markedly beneficial effect. Some have been treated some months ago, and are still free from any recurrence.

I have constantly been asked if this treatment by caustics is not very painful. I was myself much surprised on seeing the patient the day after operation to find they one and all expressed themselves as suffering no pain whatever, and also saying that their old pain had disappeared. In several cases what appears to be the whole uterus has come away after the free application of the caustic. Here are three specimens.

The following case illustrates well the method I have described. I have now operated upon ten cases with not one fatal result, although in two cases in which the posterior wall of the vagina was implicated a recto-vaginal fistula was established:—

Emma B., æt. 37, married, 8 children; one miscarriage two years ago. Admitted into Cancer Hospital March

18th, 1893. Complains of offensive discharge, sometimes blood-stained. Also has pains in the back and shooting pains down the left leg as far as the knee. Patient first noticed the discharge a year ago; she was then seven months pregnant. She has lost much flesh. There is no family history of cancer. Patient was ordered morphia ⅓ gr. three times a day, as the pain was so severe.

Present Condition.—A large crater-like cavity in the situation of external os, easily admitting the tip of finger. The growth has extended to the vaginal walls; uterus much less movable than normal.

April 8th, 1893.—Under ether the growth and whole of interior of the uterus was removed with the dredger. The cavity thus left was packed with chloride of zinc wool. The vagina was then plugged with tampons of wool which had been squeezed out of strong solution of carbonate of soda and water.

April 10th.—Vaginal plugs removed. Vagina well syringed out through a Fergusson speculum. Dry tampons placed in vagina. The vagina was syringed out three times a day

April 12th.—Chloride of zinc wool removed from uterus, which was well douched out with 1-40 solution of carbolic acid.

April 13th.—Much offensive discharge and large sloughs removed.

April 18th.—No discharge or pain to speak of. Patient expresses herself as much better.

April 19th—Uterus again plugged with chloride of zinc wool and vagina packed with tampons squeezed out of carbonate of soda solution.

April 21st.—Chloride of zinc wool removed.

April 22nd.—Much offensive discharge and sloughs.

On May 21st, as there appeared to still be some growth remaining, the cavity was again plugged with chloride of zinc, which plugs were removed on May 23rd.

June 1st.—Patient discharged: has no pain or discharge to speak of, feels much stronger, and expresses herself as feeling quite well.

Aug. 3rd.—Still continues free from pain or discharge; the parts feel quite firm.

◆

OTORRHŒA AND ITS DANGERS.

By STEPHEN PAGET, M.A., F.R.C.S.,

Surgeon to the Metropolitan Hospital and to the West London Hospital.

(A Post-Graduate Lecture, Metropolitan Hospital.)

The bills of mortality for England show that the number of deaths every year from otorrhœa is about 500. To these we must add a yet larger number of deaths returned under such headings as meningitis and brain disease; and we shall probably be well under the mark if we say that every year, in England alone, the death-rate from disease of the middle ear is near 1,500 (*a*.) Nor can we wonder at this, when we consider how these deaths occur. We have to deal with a labyrinth of small cavities, from which the pus may be unable to escape: it is exposed to the air inside the mouth by the Eustachian tube, and to the outer air by the perforated membrana tympani, and thus it becomes thick and septic: there is nothing to check the advance of caries, and everything to favour it: the base of the brain, the under aspect of the temporo-sphenoidal lobe, the cerebellum, and the lateral sinus, are all in the immediate neighbourhood.

Truly prevention is better than cure; but until people think more seriously of earache we cannot do much as regards prevention. So much might be done: the removal of enlarged tonsils, and of adenoid growths: the arrest of the miserable earaches of children by the use of Politzer's bag: the teaching that the children must keep their mouths shut, and breathe through their noses; the careful watch for any sign of inflammation of the ear in scarlet fever, measles, and diphtheria: the arrest of the impending perforation by making a minute puncture through the membrane. But so long as mothers take their children's earaches as a matter of course, so long the death-rate will remain ten times what it need be.

Let us, then, take the cases where otorrhœa is already in full swing. Let us never fail to examine the membrane. Just as we make a rectal or vaginal examination, so in all cases of otorrhœa let us examine the membrane. It is a great advantage to hold a lens in front of the speculum. The mirror should be worn on the forehead, for two reasons: first, that we may look straight down the middle of the ray of light, and next, that we may have both hands free. We lose both these advantages if we hold the mirror in our hand: and the worst way of all is to hold the mirror between the teeth. I always use Brunton's otoscope: it pours a flood of light on to the membrane, and it contains a strong lens to magnify it.

The healthy membrane is a delicate greyish or yellowish white, with a tinge of rose-pink in it; and it has a fine curved lustrous surface like a pearl, or like the inside of a shell. That part of it which lies just below and in front of the insertion of the malleus catches the light more than the rest, and this bright triangular spot is called the cone of light. The malleus, of a clear ivory tint, is sharply defined, but does not stand out to any marked extent. That part of the membrane which lies just above the head of the malleus is called Shrapnell's membrane: it deserves attention, because perforations of Shrapnell's membrane are easily overlooked: they are, moreover, difficult to heal. In some membranes, where the head of the malleus is more prominent than usual, one sees two well-marked elevations of the membrane, one on each side of the malleus: these are the anterior and posterior folds of the membrane. There is as much variety in the healthy membrane as in the other features of our faces; slight differences of size and tint and curve: some membranes lie near the surface, others lie deep: in some the malleus is almost vertical, in others it is almost horizontal; in some we can clearly see the incus lying behind the malleus.

We are not concerned now with any changes in the membrane save those that are associated with otorrhœa. Let me only mention the two most common of them. 1. The so-called "retraction" of the membrane that we see so often in cases of deafness from repeated colds in the head, enlarged tonsils, or adenoid growths. This is not true retraction from shrinking or cicatrisation of the membrane; but the obstruction of the Eustachian tube hinders the passage of air up from the mouth into the cavity of the tympanum, and thus the weight of the atmosphere on the surface of the membrane, being unopposed, pushes the membrane inward; the malleus stands out so sharply that it looks ready to jump through the thin membrane stretched over it; and the natural concavity of the membrane is so increased that the cone of light is displaced or broken or lost. 2. The thickening of the membrane in those cases of intractable deafness which are most common toward old age. It loses its pearly lustre and its delicate texture: it becomes dull and opaque, of a dead-white tint, with traces of fibrous tissue in it, which give it a scarred, striated appearance.

But let us limit ourselves to otorrhœa and its dangers. Otorrhœa may, of course, occur without perforation. Very young infants sometimes have a slight discharge of clear thin fluid from the ear, not preceded by earache or by sore throat, and lasting only a few days: it is probably due to mere irritation of the meatus, like those raw moist patches that come in the folds of their necks and groins. True eczema of the meatus, at

---

(*a*) C. A. Ballance, Med. Soc. Proc. 1890.

any time of life, may cause a thin irritable discharge from the ear: it may be tinged with blood, and is attended by troublesome itching, and sticks to the auricle in thin scabs. Foreign bodies in the meatus—such as beads and pebbles—may cause otorrhœa, though there is no perforation; and so, of course, may an abscess of the floor of the meatus. But in nine cases out of ten, where there is otorrhœa, there is perforation.

In some few cases perforation is due to external violence—a box on the ear, a violent kiss on it, a loud explosion near it, the meddlesome introduction of a hairpin into it, the presence of a foreign body. In most of these cases we find a narrow irregular slit or a minute laceration of the membrane, but no diffuse inflammation of it: such cases as a rule heal rapidly without suppuration. But perforation by a foreign body is a more serious affair: a large hole is made in the membrane, and there is acute inflammation of it, and of the tympanum. But in the vast majority of cases perforation is due to acute inflammation of the middle ear. There is the history of earache, and in most cases of frequent earaches in childhood: then comes one earache worse than the rest, two or three days and nights of intense depressing pain, tenderness, throbbing in the ear, headache, feverishness, the usual domestic remedies, then the sudden delicious relief of perforation, and a quiet night for everybody, dearly purchased at the cost of a hole in the child's membrane, which may be followed by caries, and then by erosion of the mastoid, or the upper or posterior aspect of the petrous, and then at last by infection of the meninges, or the brain, or the lateral sinus.

Unhappily, we seldom see these cases till the damage is done. If we do get such a case at its earliest stage, before the membrane is acutely inflamed, the use of Politzer's bag may stop all further trouble. In a later stage, when the whole membrane is scarlet and swollen, or we can see a drop of pus bulging behind it, we must give an anæsthetic, get a good light on the membrane, and puncture it with a paracentesis knife, or a fine sharp tenotomy knife, thus relieving the pain, arresting the inflammation, and evacuating the pus with the least possible damage to the membrane.

But let us take the rank and file of the cases where perforation has already occurred. Let us note the character of the discharge, whether it is mixed with blood, or with thin shreds of fibrin, or with hard flakes of caseous pus: whether it is offensive, not forgetting that pus which is not offensive may yet cause pyæmia by infection of the lateral sinus; there are plenty of cases to prove this. Let us note also whether the lotion passes into the mouth or nose; this of course proves that the membrane is perforated, but tells us nothing of the size or character of the perforation. Then, having carefully cleansed and dried the meatus, we examine the membrane. We note the presence or absence of a foreign body, or of a polypus. If granulations are present, we note their size and their point of origin; we see whether they are of recent growth, sensitive, vascular, bleeding from the mere passage of the lotion over them, or pale, flabby, indolent, and sodden with discharge. If there are no granulations, and nothing obstructs our view of the membrane, we note carefully the size, shape, and position of the perforation; we look to see if the membrane is perforated in more places than one, though this is rare. We examine the margin of the perforation, to see if it has that narrow edge of white that is a sign of healing; and we note whether the rest of the membrane is inflamed, or healthy, or scarred with old adhesions. It is easy to overlook a small perforation, especially in Shrapnell's membrane. But in most cases a few drops of lotion remain in the ear after we have syringed it, and these rise and fall with the pulse in the carotid, so that we see a bright point of light dancing up and down, or backward and forward, keeping time with the pulse, and this dancing bubble is a sure sign of perforation.

As regards the treatment of simple otorrhœa, I can add nothing to the teaching of those who speak with authority, or to the ordinary practice in such cases. We have to deal with a small deep abscess-cavity, inside a bone which easily becomes carious; the abscess-cavity cannot protect itself from septic and putrefactive organisms, and cannot drain, save at haphazard, and uphill, through a minute hole in an unyielding membrane. Our duty, therefore, is to cleanse it and drain it. To drain it, by the careful removal of all obstructions, such as polypi and granulations; to cleanse it, by diligent and vigorous syringing three or four times a day, and by the use of boracic acid, either packed into the meatus, or blown into it through a quill after each syringing. And if the perforation be small and recent, we must not use any boracic acid; it would only stop the drainage, and do more harm than good. As to the removal of granulations, I believe that astringent powders and lotions are worse than useless; they require chromic acid, forceps, curette, or galvanic cautery. And, for all that we can do, 25 or 30 per cent. of the perforations that we treat are incurable. A perforation that involves a third, or more than a third, of the membrane will never close; it will at best only come to a standstill by adhesion of the remains of the membrane to the back-wall of the tympanum.

As regards the dangers of otorrhœa, we may arrange them as follows:—

1. Abscess outside the mastoid.
2. Abscess inside the mastoid.
3. Invasion of the meninges, or the lateral sinus, or the brain, or of two of them, or all of them together.

All these dangers, with the exception of some of the abscesses outside the mastoid, where the pus finds its way between the bony meatus and the cartilage of the ear, come from the same cause: they all begin with caries of the tympanum and of the mastoid cells. Just as a carious tooth goes on to abscess at the roots, periostitis of the jaw, alveolar abscess, and abscess in the neck, so, more slowly and uncertainly, caries of the tympanum works its way either outward to an abscess outside or inside the mastoid, or backward to the groove for the lateral sinus and the posterior fossa of the cranium, or upward to the temporo-sphenoidal lobe and the base of the brain, or downward under the deep cervical fascia into the neck.

It is impossible to draw hard and fast lines. Abscess outside the mastoid is usually due to abscess inside the mastoid; abscess inside the mastoid may put on all the symptoms of intra-cranial disease; intra-cranial disease has no one set of symptoms, and may attack the meninges, the lateral sinus, and the brain, separately, or two at a time, or all three together. Let us then make a fresh division of the cases, not according to what we expect to find when we operate, but according to what we did find when we operated, or, in fatal cases, what was found *post-mortem*. Let us divide the cases thus:—

1. Cases where the disease has not yet passed inside the skull.
2. Cases where it has already done this.

Let us call the first set of cases extra-cranial, and the second set intra-cranial; and let us begin with the extra-cranial cases.

Cases do occur, though not often, where an abscess outside the mastoid seems to be really a simple abscess, not due to caries of the bone; no bone is felt when the abscess is opened, and it heals like any other abscess. Thus, in a baby 9 months old with otorrhœa, I opened a large acute abscess over the mastoid: no bare bone was felt, and the cavity healed quickly without drainage. In a girl, æt. 8, where otorrhœa had been followed by periostitis of the floor of the meatus, I opened an abscess over the mastoid, but found no bare bone. Perhaps in such cases as these the pus escapes not through the mastoid, but between the bony meatus and the cartilaginous meatus.

But these cases often come back, and we are told that the abscess healed, but afterwards the scar broke down, and then it healed again, and then broke down again, and so on. Practically, pus outside the mastoid is a pretty sure sign of pus inside the mastoid.

Let us take the extra-cranial cases all together, and let me begin with two cases of chronic inflammation inside the mastoid, suddenly giving rise to very acute inflammation.

1. A boy, æt. 15, with chronic otorrhœa, had suffered for a week or ten days from severe pain, with headache and feverishness. He was now very ill; foul tongue, rapid pulse, temp. 101·3°, face flushed. Behind his ear was an acute sub-periosteal mastoid abscess, pushing the auricle forward; inside the meatus was a large polypus. The glands in the neck were swelled. I gave ether at once, and removed the polypus, and let out a lot of very foul pus that was pent up behind it, more than two teaspoonfuls. I scraped out the tympanum, scooping out a lot of half-solid pus, caked into a plug. I opened the mastoid abscess, and found the bone bare and rough, with a wide hole in the meatus, through which I passed a tube.

2. A boy, æt. 12, with otorrhœa for many years. Present illness began a fortnight ago. He was now desperately ill; frequent rigors, vomiting, temp. from 101° to 103°, tongue coated, face flushed, skin hot and dry, intense continuous occipital headache, with pains down the back; most alarming of all, he had that slow pulse, 60-70, which in such cases suggests cerebral abscess. There was also slight facial paralysis on the diseased side. But his mind was quite clear; there was no rigidity, spasm, or paralysis of the opposite side of the body, no retraction of the head, no fulness of the jugular vein in the neck. Lastly, there was no swelling over the mastoid, and no tenderness of it.

I trephined over the mastoid, but too far back, and only exposed the lateral sinus. I pricked this to see if it was occluded by a septic clot, but only a little blood came. I extended the trephine hole forward and downward into the mastoid, and opened a small cavity containing 15 or 20 drops of thick pus. I scraped out the tympanum, removing a dead polypus, and syringed right through, and packed the wound with gauze.

These were chronic cases, which were made acute by a polypus blocking the outlet of the discharge. More often we have to deal with simple slow caries, or necrosis, or chronic abscess of the mastoid. The following are cases of simple caries or necrosis:—

1. Child, æt. 3. Otorrhœa for 18 months. Sinus behind the ear. Facial paralysis. (*a*) Removed a large sequestrum from anterior aspect of mastoid. Several crumbs of bone afterwards worked their way out through the ear. Sinus healed. Facial paralysis remained.

2. Child, æt. 1 year 10 months. Mastoid abscess had been incised when child was three months old, and had never healed. Otorrhœa. Sinus behind ear, leading to dead bone. Sinus was laid open, and bone was removed, but this had to be done again three months later, and then it healed.

3. Child, æt. 2½. Abscess incised a fortnight ago, did not heal. Probe passes forward over bare bone, and then slips into a sinus in the bone, with soft carious edges. I found this sinus in the bone plugged with vascular granulation tissue, scraped it, and removed a soft sequestrum from it.

4. Child, æt. 2½. Abscess had been incised, and healed, and then had broken down again, and remained unhealed for five or six months. Sinus in soft parts, leading to a very narrow sinus in the bone; this I scraped and explored, without finding a sequestrum, but at last I found at the end of the sinus a very small cavity containing a soft sequestrum. A few weeks later, the sinus had to be scraped again, then it healed.

5. Child, æt. 3. Right mastoid had already been operated on for a sequestrum. I now removed a similar sequestrum from the left mastoid.

These five cases, all under three years old, show that the usual condition in very young children, whose tiny mastoids offer no opposition to the spread of inflammation, is that of caries or necrosis. In older children, and in adults, the mastoid makes a stand against invasion, and so we get a chronic abscess locked up in a shell of bone, as in the following cases:—

1. A girl, æt. 10. Otorrhœa 4 years, with attacks of pain in the mastoid, and headaches, meatus blocked with granulations, slight œdema over mastoid. Trephine over the mastoid exposed a cavity as big as a hazel nut, plugged with foul half solid pus. Syringed through abscess cavity and tympanum, and passed a drain through, and out at the auricle.

2. A boy, æt. 7. Otorrhœa since infancy, with attacks of pain in the mastoid, and headache. Meatus blocked with granulations; mastoid greatly enlarged, half as large again as the opposite mastoid, but not tender. Trephine applied too far back, so that lateral sinus was exposed. Large cavity in mastoid, containing a few drops of pus and half a teaspoonful of foul half solid caseous matter. Cavity scraped and washed out; drain passed through, and out at the auricle.

3. A girl, æt. 10. Otorrhœa 5 years. Sinus over mastoid; probe passed forward over bare bone, then slipped into a sinus in the bone, and came out coated with caseous pus. Sinus in bone was found to lead into a cavity the size of a hazel-nut, full of foul caseous pus. I could not find an opening into the tympanum, so I cut the bone away in front of the cavity, and made a free opening into the bony meatus.

4. A girl, æt. 12. Otorrhœa 4 years, due to measles. She has also had two operations for adenoid growths, and has had polypus or granulations twice removed from the ear. A few months ago abscess over the mastoid, which broke and healed and broke again and again. A large gland in the neck; sinus behind ear, fringed with flabby granulations; ear blocked with similar granulations. The soft parts behind the ear were laid open, and rough bare bone was found. After careful search, a sinus in the bone was found just behind the meatus, and a probe passed into it came out coated with caseous matter. The sinus led into a cavity, the size of a hazel-nut, full of caseous pus. I scraped out the tympanum and syringed through, and passed a drain right through, and out at the auricle.

5. A man, æt. 40. Otorrhœa, headaches, pain, and tenderness over mastoid. In the mastoid a large cavity plugged with caseous pus.

I will not trouble you with more cases; let me only give one curious case where the disease extended not only outward into the mastoid cells, but also downward beneath the deep cervical fascia:—A child, æt. 2 years, 8 months; otorrhœa after scarlet fever. I opened an abscess over the mastoid, and removed some carious bone. A fortnight later an abscess came beneath the angle of the jaw, and we found that this communicated with the abscess cavity over the mastoid, and also contained some crumbs of bone. Six weeks later there was empyema of the same side of the chest; this was aspirated, and afterwards drained with resection of rib, but the child was feeble and pulled down, and died a week later. It seems, therefore, that empyema may be started by caries of the

---

(*a*) The prognosis as regards facial paralysis in suppurating disease of the middle ear depends chiefly on the patient's age. In infants and very young children, it is much less likely to pass off than in older children and adults.

floor of the tympanum, allowing pus to track under the deep cervical fascia into the chest.

Here let me mention two conditions that occur, though not often, in these cases of caries, or of chronic abscess :—

1. Caries of the tympanum does sometimes occur without any perforation of the membrane, and thus without any otorrhœa. True tubercular caries may start in the tympanum, as it may start in the head of the tibia, or in any other bone in the body, and may even eat its way through the petrous bone and set up intracranial disease, without ever perforating the membrane. Therefore, if there are other signs of disease of the middle ear, we must be ready to operate, even though there is no otorrhœa.

2. In older children, and in adults, the mastoid may offer so much resistance to the spread of inflammation that it becomes much thickened or even quite solid; one chisels away at the mastoid without finding anything but a solid block of bone. I have more than once met with this vexatious failure. But I suspect that it has been my own fault, and that I have not been chiselling quite straight for the mastoid antrum. Still, this solidification or sclerosis of the mastoid does sometimes occur, and we must bear in mind the possibility of it.

I speak of "chiselling quite straight for the mastoid antrum." Happily, in many cases, we find a carious sinus in the mastoid that leads us at once to the seat of the disease: and in other cases the whole mastoid is plugged with a caseous abscess so big that we cannot miss it: but in cases where we have no guides like these, we must go straight for the antrum. These specimens show it freely exposed, and show that it lies immediately behind the upper part of the bony meatus. If we go higher up, we get into the cranial cavity. If we go further back, we get into the groove for the lateral sinus. MacEwen's guide to it is the spot just between the meatus and the posterior root of the zygomatic arch; what he calls the "supra-meatal triangle." To open the mastoid, one ought not to use a trephine, but a small gouge or chisel with a mallet. MacEwen uses a rotatory burr driven by a surgical engine, but for ordinary practice the chisel and mallet answer all purposes. A good drain through, in at the mastoid, and out at the external ear, may be made with thick pewter wire, and this drain must be kept in place for many weeks, perhaps seven or eight.

If we review our experiences of these extra-cranial cases, we find that they may be divided into two chief groups, according to the patient's age. In very young children, whose mastoids make no stand against the spread of inflammation, we get rapid caries or necrosis, and this wins an easy victory without any acute pain or marked disturbance of the general health. In older children and in adults the bone resists invasion, and we get a chronic abscess locked in a shell of bone, or there may be a narrow sinus in the bone, so that a probe, passed through a sinus in the soft parts over the bone, slips forward over the bone, and then dips into the sinus in the bone, and comes out smeared with thick pus.

We find also that the spread of disease to the antrum and mastoid cells may from the beginning run an acute course with alarming symptoms, or this acute and alarming condition may suddenly arise in a chronic case. Fever, shiverings, vomiting, intense headache, a foul tongue, a quick pulse, loss of sleep, loss of flesh, even optic neuritis may occur in such cases, and it is probable that in some of them the petrous is already perforated, and pus or granulation tissue has begun to collect between the dura mater and the bone. In the two cases I read first, it seems probable that this had occurred, from the gravity of their symptoms and from the very large quantity of pus that was evacuated in the first case. These cases, therefore, are not truly extra-cranial; they are intra-cranial, but extra-dural. They lead us to the consideration of that large and terrible group, the intra-cranial cases.

I am ashamed to talk of these intracranial cases when such magnificent work has been done by Ballance, Horsley, Arbuthnot Lane, and others; above all by MacEwen. Look at Ballance's papers in the "Medical Society's Proceedings," for 1890, and in the *Clinical Journal* last autumn; Horsley's splendid achievements in brain surgery; Lane's paper in the *Lancet* last year; above all, MacEwen's record of his wonderful insight and skill in saving these lives. (*a*) I can only offer you what I have stolen from these masters of surgery, together with some of my own cases, mostly failures.

CASE I.—*Extradural Abscess on Posterior Aspect of Petrous Bone.—Septic Thrombosis of the Lateral Sinus.—Pyæmia.*—Five years ago I operated on a boy, æt. 8, who had suffered from otorrhœa off and on since infancy. He fell ill, a week before the operation, with vomiting, diarrhœa, and attacks of faintness. On admission, September 13, he was drowsy and heavy; slight swelling and tenderness of mastoid; headache; temp. 103°. Sept. 14 he was much better, save that his temperature rose to 105·2°. Sept. 15 he had a slight rigor. Next day I opened the mastoid, but no pus flowed from it. I then exposed the lateral sinus, and passed a probe forward and inward between the dura mater and the posterior aspect of the petrous bone, and let out some thick pus, with bubbles of foul gas, and put in a drainage tube. But he got no better, and died next day.

Post-mortem.—The tympanum was full of pus, and its walls were carious. My opening in the mastoid stopped 1-6th inch short of a caseous deposit in the antrum, no bigger than a pea. This communicated with the tympanum, and also with the abscess between the dura mater and the back of the petrous bone. The posterior aspect of the petrous bone was rough and bare. The dura mater over it had sloughed, and a probe could be passed straight into the lateral sinus. Inside the lateral sinus were two or three small loose round pale clots. The lungs were full of minute pyæmic emboli.

CASE II.—*Mastoid Abscess.—Cerebrellar Abscess.—Sudden Death.*—Last September a man, æt. 40, was admitted here. Right otorrhœa began two years ago. One year ago, pain in the right mastoid, headache, and abscess over the mastoid, which was incised, and healed. Present illness began a few days before admission with intense headache, wandering at night, and vomiting. He was admitted Sept. 8th; no vomiting then, no rigors, no pain, only headaches. Sept. 13th I opened the mastoid, and found a small sinus leading into a cavity with a drop of foul pus in it. This I drained with a strip of gauze. He got better, his temperature fell to normal and stopped there, and he went out on Sept. 22nd. A week later the headaches and wandering at night returned, and he was readmitted. Again he seemed to improve in hospital; no vomiting, no rigors, no marked rises of temperature; nothing but headaches and slight, very slight, drowsiness and dulness and depression; he did not get worse, but he did not get better. Oct. 6th I again explored the mastoid, but found nothing more in it. Oct. 7th he seemed doing well. That evening he become drowsy and delirious. Oct. 8th he suddenly became unconscious: vomiting, twitchings of the arms, slow laboured breathing, and death.

Post-mortem.—Pus in and around the middle ear. The cerebellum was adherent to the posterior aspect of the right petrous bone, and the whole right lobe of the cerebellum was destroyed by a large abscess; its surface was greenish and half melted, its convolutions were all shredded out and diffluent.

(*a*) "Pyogenic Diseases of the Brain and Spinal Cord." Glasgow, 1893.

Case III.—*Extradural Abscess.—Basal Meningitis.—Death.*—A girl, æt. 15, was lately admitted to the West London Hospital with headache and delirium. No history of otorrhœa was given, and it was thought the case might be one of typhoid, especially as there was never any vomiting. But she had the following symptoms: 1. Acute onset of illness; 2, well marked retraction of the neck; 3, rapid emaciation; 4, restless busy delirium, never ceasing, and plucking at the bedclothes; 5, she passed everything under her; 6, temperature always high, pulse always rapid 140-170, pupils always dilated and fixed. It seemed certain, though she had no vomiting, no marked optic neuritis, and no paralysis, except a slight weakness of the right internal rectus shortly before her death, that she had basal meningitis, and I did not operate. We got a history of earache some few weeks ago, followed by discharge, and she had a small recent perforation of the left membrane.

Post-mortem.—The whole base of the brain was matted with firmly adherent lymph, and soaked in fœtid pus. On the under aspect of the left temporo-sphenoidal lobe was a dark stain the size of a three-penny bit, and here was a tiny abscess between the upper aspect of the petrous bone and the dura mater.

Case IV.—*Otorrhœa.—Temporo-Sphenoidal Abscess.—Recovery.*—A boy, æt. 12, was under my care with left otorrhœa, followed by constant intense headache, shivering, and giddiness. Then came a week of cerebral irritation. Then came vomiting, drowsiness, optic neuritis, and paralysis of the opposite side of the face, and some loss of power of the opposite hand. I trephined over the left motor area, and let out an ounce of pus; but my trephine hole was too high, and I trephined again lower down. He recovered, but it would have been better if I had trephined lower down to begin with. (*a*)

These four cases and these specimens show the four chief ways in which the disease strikes at the patient's life. 1. Lateral sinus pyæmia. 2. Cerebellar abscess. 3. Basal meningitis. 4. Temporo-sphenoidal abscess. And it may strike two or three ways at once.

I have neither the time nor the right to speak with any authority of these cases. First, we must make our diagnosis, remembering that the otorrhœa may be slight and free from smell, and that it may even be absent, inasmuch as tubercular caries of the tympanum may occur without any perforation of the membrane. Let us not mistake typhoid for pyæmia, nor pyæmia for typhoid. Let us exclude cases of simple acute or tubercular meningitis of the base of the brain. Let us bear in mind the chief signs of lateral sinus pyæmia—the acute onset, the repeated rigors, the temperature rushing up and down, the tenderness and swelling of the internal jugular vein in the neck. Let us bear in mind the chief signs of cerebral abscess—the insidious onset, the curiously normal temperature, the slow pulse. Finally, and above all, let us remember that prevention is and always will be better than cure; let us attack these dangerous half-rotten mastoids as we would attack a whitlow in the finger or a cancer in the breast. Let me end by quoting from MacEwen's magnificent book: "All persistent purulent discharges from the middle ear ought to be regarded seriously. . . . . The disease progresses insidiously, and one cannot be certain as to where and when it may end. . . . It becomes a standing menace to the safety of the patient. . . . A person might as well have a charge of dynamite in the mastoid."

Selected Prescriptions and Therapeutic Notes.

154.—For Erysipelas:—

℞ Ichthyol, ℥ss;
Ætheris, ʒijss;
Glycerini, ʒij.

M. To be painted over the affected skin.—Lorenz.

155.—Local Application for Burns:—

℞ Saloli, ʒss;
Liq. calcis, ℥iiss;
Ol. olivæ, ℥ij.

M. Strips of lint to be soaked in the solution and applied to the affected parts.—Nicot.

156.—For Acute Coryza:—

℞ Cocainæ hydrochloratis, gr. vj;
Bismuthi subnitatis, ʒss;
Talci, ʒiss.

M. Enough to cover a sixpenny piece to be insufflated into each nostril every two hours.—Sajous.

157.—Useful in Flatulence:—

℞ Olei cajuputi, ʒss;
Tinct. lavendulæ co., ℥ss;
Mucilaginis acaciæ, ad. ℥ij.

M. A desertspoonful when necessary.—Hartshorne.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, June 6, 1894.

The President, Dr. G. E. Herman, F.R.C.P., in the Chair.

A CONTRIBUTION TO THE STUDY OF TUBAL MOLES.

Mr. Bland Sutton showed a specimen taken from a woman, æt. 35, who had had several children, the last fifteen years ago. In April last she missed a period for the first time since fifteen years, and fourteen days later she complained of sharp pain in the pelvis. This became so severe that she was obliged to keep her bed. On the 29th she was seized with a violent attack of pain in the pelvis and shortly afterwards she became collapsed. When seen, she was quite blanched and the pulse was scarcely perceptible. On percussion, the abdomen was dull, and *per vaginam*, the recto-vaginal pouch was felt to be distended with fluid. He performed laparotomy two hours later and found an ovum protruding from an opening in the right Fallopian tube. The patient unfortunately succumbed 60 hours after the operation. The specimen consisted of a tubal mole with the remains of the fœtus lying in its own membranes and surroundings with chorionic villi. He explained that in an ordinary fœtal sac, outside was the chorion, with its villi, and inside this, at one end, was the amnion, inside which again were the fœtal remains, the allantois, &c. Between the amnion and the chorion there was a space, at any rate a potential space, which was usually filled with an albuminous fluid. This space persists for some weeks and as it did not appear to have received any name so far, he designated it as the "sub-chorionic chamber." As the amnion increased in size this space was impinged upon and ultimately the amnion came into contact with the chorion, just as the pleura is in contact with the thoracic walls. This, he thought, threw some light on the mode in which tubal moles were formed. In the specimen before them this sub-chorionic space could be seen to be filled with blood. This specimen, he thought, proved that a mole is formed by the effusion of blood into the sub-chorionic chamber, pressing the amnion to one side, as the lung is compressed by a pleuritic effusion. This blood, he inferred, must come from the vessels of the allantois and it followed as a corollary that the causes which determined the formation of a tubal mole arose within the ovum itself. He brought the specimen forward as a contribution to their knowledge of what Sir William Priestley had so aptly entitled "The Pathology of Intra-Uterine Death."

The President observed that in his own cases the blood has always been outside the amnion. At the same time he failed to see why, in some cases at any rate, the blood should not come from the chorionic vessels, the blood crumbling in the chorion.

Dr. Horrocks asked whether it would not be possible by a careful examination, to ascertain whether the blood in these moles was maternal or fœtal? He protested against the author's inference that hitherto it had been exclusively taught that apoplectic ova are due to hæmorrhage from the mother.

Dr. H. Spencer asked whether the author's conclusions applied only to the formation of extra-uterine moles, and he alluded to a specimen closely resembling the author's of which a description had appeared in last year's "Transactions." He had shown it as a gestation which, if it had continued to develop, would probably have become a placenta prævia.

Mr. Bland Sutton, in reply, said he had very little opportunity of studying the intra-uterine mole, and though he had looked up obstetrical literature to find some description of their formation he had been unable to discover anything on the subject. The specimen opened up a wide question which he hoped one of these days to bring before the Society when they would have an opportunity of discussing it *in extenso.*

LIGATURE AND DIVISION OF THE UPPER PART OF THE BROAD LIGAMENTS COMPARED WITH REMOVAL OF THE UTERINE APPENDAGES.

Dr. Leonard Remfry read notes of a case illustrating the effects produced by ligature and division of the upper segments of the broad ligaments. The patient was 47 years of age, and had been under treatment as an out-patient for metrorrhagia due to a large fibroid uterus. In August, 1891, as her condition steadily became worse, it was decided to remove the appendages, but this proved to be impossible in consequence of dense adhesions. The ligatures were, therefore, passed through the upper part of each broad ligament, one close to the uterus, the other but one inch away, including the Fallopian tube and ovarian artery. The latter were then divided. The patient made a good recovery, and no metrotaxis followed the operation. All went well until the end of the third month when the metrorrhagia returned, and soon became as profuse as ever. Six months later the uterus was removed by the extra-peritoneal method, through the abdomen, and the patient was soon quite well. He alluded to the difference of opinion that prevailed as to why removal of the appendages so generally put a stop to menstruation. Lawson Tait, for instance, attached most importance to removal of the tubes. Dr. Johnston (*American Gynæcological Journal*, 1888) thought that menstruation was governed by a nerve trunk which ran in the angle between the round ligament and the Fallopian tube. Menstruation, however, did sometimes persist after removal of both ovaries, and it seemed possible that the effects of oöphorectomy might be due to lessening of the blood supply consequent on the operation. In this case the ovarian artery was tied near the uterus so that its branches to the broad ligament, &c., were left intact. The uterus itself, however, was thereby deprived of its blood by that channel, thus producing temporarily the same condition as that induced by oöphorectomy. Dilation of these vessels might very possibly enable the same quantity of blood to be brought to the uterus, and this, he suggested, took place in his case. In oöphorectomy a considerable segment of the ovarian artery was removed, and so the collateral circulation would not be established. The blood supply of the uterus is, therefore, restricted to that derived from the uterine artery.

Dr. Horrocks said he had never seen a case in which both ovaries had been *undoubtedly* removed without the hæmorrhage ceasing, at any rate, after a time, though he had heard of this being the case after both ovaries were *said* to have been removed. He had been quite unable to find the nerve trunk described by Dr. Johnston, and until its existence had been demonstrated it was unnecessary to discuss its physiological function. He suggested that temporary arrest of menstruation might be due to the shock of the operation, examples of which were by no means rare, and he referred to the case of a young lady who was frightened by burglars, and who, thereupon, ceased to menstruate for five years.

Dr. Duncan said he had under observation four patients in whom he had undoubtedly removed both ovaries completely, yet the operation had been followed by profuse menorrhagia. These were the only instances out of a large number of operations for removal of the appendages in which the hæmorrhage had continued. He confessed himself unable to account for the continuance of menstruation in these cases, and suggested that possibly it might be due to the irritation produced round the stump by the ligature, thus keeping up the flow. With a ligature tied tightly he could not see how the fact of there remaining a small portion of ovarian tissue on the distal side could influence menstruation.

The President alluded to a paper which had appeared last year in one of the medical journals advocating ligature of the broad ligaments as a means of checking the growth of cancer, a case being recorded in which this was done. No effect was produced on menstruation. He also mentioned a case by Murphy, of Sunderland, in which, failing to remove the ovaries, this surgeon had tied the broad ligaments, but without effect. If he had hæmorrhage after removal of the ovaries he would assume that he had not removed them completely.

Dr. A. Routh said he had seen three such cases, and in two the uterus was subsequently dilated and a polypus found in its cavity, while in the third case there was "fungoid endometritis." One or other of these conditions might account for the continuance of the hæmorrhage without assuming that any ovarian stroma had been left. These cases conveyed the lesson that it would usually be well to explore the cavity of the uterus before proceeding to any severe operation. Removal of the appendages involved the ligature or removal of the ovarian arteries, &c., together with any nerves from the sympathetic ganglia, and he pointed out that even if the ovaries did control menstruation it must be through the medium of the ganglionic nerves.

Dr. Remfry, in reply, admitted that no one had, so far succeeded in discovering the nerve trunk described by Johnston. The amenorrhœa in his own case might have been due to the shock of the operation, but it had lasted for three months. The shrivelling of the ovary had nothing to do with the cessation of menstruation at the menopause, and was only part of an atrophic process affecting all parts of the reproductive apparatus.

ADENOMA OF THE VAGINAL PORTION OF THE UTERUS.

Dr. Braithwaite (Leeds) contributed notes of the case of a woman, æt. 54, who was admitted in September, 1893. She was worn-looking and in poor general health. She had had several children and four abortions. Menstruation had ceased at the usual period, and she had remained free from discharge of any kind until two years ago, when a yellow fluid began to come away, not abundant but constant. No pain was complained of. On examination a shallow ulcer was seen on the left of the vaginal portion of the cervix, the base of which was a little below the base level of the surrounding surface, and was of a dark red colour, thus contrasting with the hue of the surrounding mucous membrane. It measured two-thirds of an inch across, and was circular in shape. It bled freely when touched even gently, but appeared quite superficial. The history and the appearances were against its being cancer, but he removed it by dissection, and thoroughly curetted the base, subsequently applying zinc paste to make sure of getting away all the diseased tissue. In a few weeks the patient left the hospital in good health. The tissues were somewhat more friable than normal. Sections showed it to be a glandular adenoma, the ducts being lined with a single layer of epithelium. He suggested that adenoma of the uterus might not, as was usually supposed, be invariably malignant. There had, so far, been no recurrence of the disease.

Dr. Dakin said the growth, from the sections, appeared to be a kind of adenoma not at all uncommon in the uterus, a condition in fact which might be met with if sections were made through the base of an erosion.

Dr. A. Routh said there seemed to be some proliferation of the columnar cells lining the ducts. Possibly the section was made through adenomatous tissue which had not yet undergone the typical malignant change.

The **President** pointed out that the author had expressly stated that there was no infiltration. As to the non-recurrence it was as yet too early for that to possess much significance.

TWO FIBROIDS AND A PREGNANT UTERUS.

Mr. **Malcolm** showed two fibrous tumours which he had removed from a patient, æt. 42. She had been under observation for ten years. She presented a large tumour on the right side reaching to the costal margin, while in the middle and on the left there was another tumour reaching nearly to the level of the umbilicus. *Per vaginam* the cervix was found to be almost out of reach and pushed forwards. There was a tender mass filling Douglas's pouch and distending the broad ligament. They had a consultation with Mr. Knowsley Thornton and Sir Spencer Wells, and they came to the conclusion that the patient was pregnant and they took the view that the mass behind the uterus might, in the course of gestation, rise out of the pelvis and leave the way clear. She was then sent home but returned three weeks later on account of severe pain. This was on May 17th, and on the 20th she unexpectedly miscarried, and the fœtus, &c., was expelled without assistance. The fœtus measured ten inches, making the pregnancy at about the sixth month. The patient did well for three days, but then the temperature began to rise and she complained of severe pain. On the seventh day as things appeared to be going wrong he performed abdominal section and found that there was one tumour of the anterior and another of the posterior walls of the uterus, the cavity of which was dragged into a horizontal plane. He performed hysterectomy as the only means of dealing with these tumours.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, June 6th, 1894.

The President, Dr. T. S. **Clouston**, in the Chair.

Patients.

Dr. **James Carmichael** showed a child in whom an exudative purulent pleuritis had been first treated unsuccessfully by incision and finally by aspiration with success. Twenty-five ounces of pus were removed.

Dr. **Norman Walker** showed two cases of rodent cancer after operation, the one excised and the area grafted by Thiersch's method, the other very freely removed and the wound covered by a plastic operation. Both operations were very successful, the first particularly so.

Mr. A. G. **Miller** exhibited three patients in whom he had excised the wrist joint by Watson's method.

Specimens.

Dr. **Edward Carmichael** showed an aneurism of the aorta with rupture into the right ventricle. Only four such cases had been recorded. In this case death was not sudden, rupture probably occurring two or three days before it.

Dr. **Bruce Murdoch** showed a specimen of overgrowth of the filiform papillæ of the tongue, a rare condition, noted in Ziegler's book, consisting in a hyperkeratosis of these papillæ forming long hairs.

Dr. **Allen Jamieson** called the Society's attention to a sample of superfatted soap containing 3 per cent. of resorcin and 3 per cent of salicylic acid as first recommended by Eichhorst, and found to be of great service in scarlet fever and ichthyosis. Duncan and Lockhart, of Edinburgh, had succeeded in making this soap, which could hitherto only be obtained in Germany.

Dr. **Alexander Bruce** demonstrated several microscopic sections of syringomyelia through the lantern. The patient from whom the sections were obtained only lived three days in hospital. The spinal cord showed great enlargement of the central canal which was surrounded by tumour tissue which in turn was surrounded by a strip of normal nerve tissue. The tumour mass, however, in places reached the surface of the cord.

Dr. **Byrom Bramwell** showed one or two sections to illustrate the occurrence of spaces or holes in the cord in simple and traumatic myelitis.

Papers.

Professor **Struthers** read a paper on

SEPARATE ACROMION PROCESS SIMULATING FRACTURE.

He showed many examples of separate acromion process which he had procured in the dissecting room, and pointed out that this condition occurred along with chronic rheumatoid arthritis as was described before by Adams in his work on the subject. He showed also one or two specimens of double separation. After stating how the separation could be mistaken for a true fracture, he proceeded to explain the occurrence as due to a developmental error in the failure of the process to unite with the spine of the scapula.

After some words from Dr. **Joseph Bell**, Dr. **Ronaldson** mentioned that he had seen some cases in children during life, one case being bilateral.

Dr. **Logan Turner** read a paper on

DISPLACEMENT OF THE SEMILUNAR CARTILAGE OF THE KNEE.

He first demonstrated the anatomy and mechanism of the knee-joint by means of lantern slides which were taken from photographs of dissected specimens, and further from others showing pathological conditions. He sought to show anatomically that the internal semilunar cartilage was more frequently displaced owing to its greater fixation, and that this occurred usually during rotation of the joint during which movement one or other of the cartilages tended to slip from the strain put on their ligamentous attachments, the internal in external, the external in internal rotation of the leg at the knee. Again it was possible to rotate the leg outwards to a greater degree than inwards, therefore the strain on the attachments of the internal semilunar cartilage was the more pronounced. Further, the ordinary position of the leg and foot in walking or running rendered the possibility of rotation out the easier, and consequently displacement of the internal cartilage the more common. Occupation had something to do with predisposition, especially if much kneeling was involved. So out of twenty-nine cases thirteen were in miners, one in a gardener, and one in a domestic servant. Kneeling had a greater effect if the posture had frequently to be changed, when the anterior attachments of the joint became stretched, strained, and more liable to rupture. In twenty-nine cases operated on by Professor Annandale, twenty-four were of the internal cartilage, two of the external, and two unspecified. In discussing the symptoms Dr. Turner directed attention to the difficulty of a differential diagnosis between such displacements and pedunculated bodies in the knee-joint, especially in the neighbourhood of the cartilages, or hypertrophy of a portion of the infrapatellar pad of fat. As to treatment when palliative means had failed the joint should be opened and the cartilage either stitched or removed. The prognosis in both cases was highly satisfactory.

Mr. **Joseph Bell**, Professor **Struthers**, Professor **Annandale**, Sir W. **Turner**, and Dr. **Cotterill** took part in the discussion.

Mr. **Miller's** paper on "Excision of the Wrist by Watson's Method" was held as read.

Paris, June 16th.

Spontaneous Dry Gangrene.

At the last meeting of the Académie de Médecine, M. Panas introduced a case of spontaneous dry gangrene of the foot which produced an interesting discussion. Besides the classical form, he said, of spontaneous gangrene due to atheroma, embolus, or thrombosis, there exists a particular variety of gangrene of which the etiology is very obscure, and of which he had recently seen a case. A man, æt. 35, of a gouty diathesis, experienced, six years ago, lancinating pains in his upper limbs, and soon after similar pains in the lower limbs, with formation of red patches on the left leg. These phenomena disappeared completely until 1893, when they returned with renewed intensity. In a few weeks gangrenous patches were observed on the great toe of the left foot and extending to the neighbouring parts. The suffering became very intense. In order to afford relief M. Panas amputated the leg in its superior third, and although the operation in itself was very successful, the sufferings of the patient did not abate. Chloral, bromide of potassium, &c., were given without result, when the speaker thought of trying salicylate of soda. The effect was almost immediate; all pain disappeared.

The microscopic examination of the amputated foot showed that the arteries and deep veins were considerably reduced in volume and obliterated, but yet no blood clot could be discovered. M. Panas was of opinion that the case was one of endovascularitis of a gouty origin or consecutive to a nervous lesion.

M. Verneuil said that the history of surgical gangrene is still enveloped in obscurity, and it is very difficult to determine the respective *rôles* played by the vascular and nervous system. It is especially so in the case of gangrene in those patients who otherwise are in the best of health. As to treatment, a careful examination should be made of the patient and his antecedents before resorting to the knife. He remembered a case of nervopathic ulcer of the leg in a woman for which he amputated, and the stump having ulcerated in its turn, he was obliged to cut successively the sciatic nerve and several other branches. At last he administered hyosciamine and the patient rapidly improved.

A Case of Somnambulism.

In the Lyons Hospital, and in the ward of Prof Lépine, is lying a patient who seems to be exciting great interest in medical circles. The man, a shoemaker, æt. 22, entered the hospital for hemiplegia. His condition having considerably improved under treatment, he was about to leave, when three weeks ago he was suddenly seized with an irresistible desire to sleep, and ever since he cannot be awakened. He gets up, eats, drinks, walks, sits down mechanically, and in fact does everything in his sleep that he is told; and although his eyes are always shut he sees perfectly—he reads through objects.

Yesterday, he said to Dr. Lépine, who was examining him: "Doctor, I am certain that you do not know how many rings you have in your watch chain." "Indeed, I cannot tell you, having never counted them." "Well, there are 39." The number was exact. He then told him the correct number of his watch. This phenomenon has been visited by several Lyons doctors, but no definite explanation has been given of the case.

Symphyseotomy.

In view of the recently reported cases which have lately drawn attention to the operation of symphyseotomy it is interesting to note a case published by Dr. Tonjan, of Toulouse, in the *Annales de Gynecologie de Obstetrique* for March, 1894. In the words of Professor Fochier, the "return to symphyseotomy contributes a progress, and a great progress," and the case above mentioned is a great progress indeed. Performed in an attic, the poverty and filth of which in the doctor's words "were worse than he had ever known," a brilliant success was the result; clearly demonstrating that an hospital theatre is not an absolute necessity. The operation was performed with little loss of blood, owing, according to the author, to the use of the "Soude-rougine d'ollier," an instrument which has a curvature adapting itself to the posterior of the symphysis and allowing of one largely denuding the under and posterior surface of the pubes and avoiding the wounding of the numerous vessels in this region. By the aid of two students of medicine who pressed the pelvis inwards he appears to have avoided any rupture or injury to the urethra, an accident hitherto causing trouble. The case made a rapid recovery, and is one more instance of knowledge and pluck overcoming the difficulties of ordinary practice. There is a great future before this operation, and we shall be pleased to receive accounts of any which may be attempted, whether successful or otherwise.

Berlin, June 15th.

Artificial Immunity against Cholera.

In the *Ztschr. f. Hyg. w. Infections Krankheiten*, Dr. Issaeff has an article reporting the results of his investigation into this subject. He observed what has been overlooked by investigators generally, that not only the product of the cholera vibrio, but also quite a number of other substances injected into the rabbit protect it against the cholera virus. The resistance may be procured by the injection, either subcutaneous or intra-peritoneal, of physiological saline solution, urine, bouillon, the blood serum of the healthy human subject, two per cent. nucleine acid, and tuberculine. This power of resistance lasts at most from 4 to 5 days, and must therefore be sharply distinguished from specific pulmonary treatment. The resistance thus procured is also only about one-fourth as powerful as that by specific protection. The author has determined the specific action of the blood serum of people recovered from cholera only begins after the commencement of the third week after the disease. Its efficacy is most marked from the fourth to the sixth week, and three months after the illness this property is completely lost. He confirms the statements of Pfeiffer and others that the protective power of blood serum is not an anti-toxic one. Neither is there any specific germicide action, and cholera cultures made on this protective serum are not less virulent than those grown upon ordinary nutrient soils.

In the face of these negative conclusions it is of all the more interest to follow the fate of the cholera vibrios in the normal peritoneum and the various immunised animals. The appliances for this are very simple. By means of a thin glass tube, the end of which is drawn out to a capillary tube, he penetrated into the abdominal cavities of guinea pigs in the different stages of poisoning, and thereby obtained minute samples of the contents of the peritoneum, which he examined microscopically and by further cultures. What he found was as follows: If a healthy guinea pig is inoculated with the maximum non-fatal dose of living cholera bacilli, a large increase in the vibrios is at first observed, and at the same time the peritoneal exudation is quite free from leucocytes (negative chemotaxis). After 7 hours the leucocytes increase in numbers until 12 to 15 hours after the injection (positive chemotaxis) the bacilli are taken up by these and destroyed. It is at this period that the symptoms of intoxication appear. From 24 to 27 hours afterwards the peritoneal contents are sterile. On the other hand a urther large development of leucocytes takes place, after

48 to 50 hours the exudation is like pus. From the 8th day the leucocytosis is feebler, and after 10 to 15 days the normal condition has returned.

In animals who have undergone the preliminary treatment there is this difference, that the period of increase of bacilli and negative leucocyte chemotaxis is shortened and phagocytosis takes place more rapidly. The protection therefore that any substance is able to afford is in direct proportion to the rapidity with which phagocytosis makes its appearance. With physiological saline solution negative leucocyte chemotaxis lasts three or four hours; in an animal carefully immunised fifteen days previously phagocytosis came on a quarter of an hour after the admission of the cholera virus, and in a guinea-pig prepared twenty-four hours before, it came on immediately, and after three-quarters of an hour the exudation was sterile. The immunisation by non-specific materials is therefore due to this change in the cell reaction, but the author is of opinion that the more powerful and lasting immunity produced by the products of the cholera vibrio is dependent on other not yet explained changes.

At the Medical Society, after the report of a case of extra-uterine gestation by Dr. Byk, Hr. Langerhans showed a preparation from a

Case of Glanders.

The man, æt. 39, had been engaged with sick horses the latter part of his life, and he himself suspected that he was suffering from glanders, because the horses had a discharge from the nostrils. He was taken ill four weeks before his admission into the Charité, and he died three days afterwards. Autopsy the same morning. Diseased patches in the form of glanders nodules were present in the skin, the subcutaneous cellular tissue, the muscles, in the whole respiratory tract, the lungs, bronchial tubes, trachea, nasal mucous membrane, the nasal cavities, the spleen, testicles, and periosteum. The medulla of bones showed more diffused disease. There was also a purulent collection in the right knee-joint. All the nodules presented characteristic appearances: they varied in size, the smallest were submiliary, the largest the size of an egg, only a few of the nodules in the skin and in the muscles had broken down into pus. The whole of the digestive tract and also the urinary were free from disease. The kidneys, which were discoloured and swollen, showed small punctiform hæmorrhages, but no glanders nodules. The liver dull and swollen, as well as the muscles. Whilst in the klinik glanders was suspected, but there was some doubt, as cultivation experiments on animals were rather ambiguous. The bacteriological examination had since confirmed the diagnosis.

Hr. Klemperer said the patient on admission was in a state of stupor with high fever, and gave the impression of grave typhoid. But opposed to the hypothesis were the facts that there was no rash, no swelling of the spleen, and no diazo-reaction. The white blood corpuscles were not increased. The patient showed purpura-like spots on the lower extremities. On the afternoon of the same day deep nodules were noticed on the muscles, œdema and purpura patches on the arms. On the third day the whole breast was covered with red papules. These nodules were the size of a nut with broken down centres. A certain streptococcus could be cultivated from these nodules, but from the blood nothing could be ascertained either by the microscope or by cultures.

Hr. Max Wolff said that microscopic examination in the case reminded him of the question of spore formation in glanders bacilli. The question was of extraordinary importance as it completely covered that of the continuance of the contagion in any place when the disease had appeared. After careful cultures and staining he had been unable to find traces of spore formations. Under certain conditions, however, it appeared that spores did exist as was proved by the fact that such glanders bacilli could be dried and yet retain their virulence for months together. The fact also that in places where glanders has broken out infection has remained for eighteen months was in favour of this. The bacilli in the case before them appeared to be unusually poisonous from the experiments performed by Langerhans the animals died with extraordinary rapidity.

Austria.

[From our own Correspondent.]

Vienna, June 15th.

Otholoogy of Permanent Deafness.

Prof. Politzer in his lecture exhibited a series of lupus preparations of the ear which had commenced with the symptoms of a dry catarrh of the middle ear followed by difficulty of hearing and finally total deafness. In other cases where deafness was present and the mucous membrane of the middle ear normal the primary changes were found in the labyrinth capsule greatly thickened and enlarged. The usual seat in these cases seems to be in the neighbourhood of the fenestræ, resembling a new formation which is principally observed over the ovale fenestra and stirrup plate of the stapes, producing ankylosis. Microscopic examination reveals a formation of normal tissue on the surface of the bone resembling that found in young ossification, extending wide ramifications with blood vessels. He showed cases in different stages where perfect deafness existed during life, and others with partial deafness, the latter exhibiting a circular form in the process of formation. One of the complete series had the ossification of the labyrinth capsule around the fenestra extending up the cochlea along the scala tympana. The microscopic section when covered with carmine exhibited a wide trabecula of bone filled with fibrous tissue, newly-formed blood-vessels, wandering cells and osteoblast. On the etiology of this formation he could not affirm that all were confined to aged persons. Neither did he think syphilitic affections could be proved in its production. No doubt Geadenigo had given undeniable proof of progressive deafness in chronic syphilis which had produced changes in the labyrinth capsule. With regard to the therapy in these cases little hope of success could be offered. The recent method of treatment in arid catarrhs of the middle ear was extraction of the stapes, which he considers contra-indicated because the new formation of bone in the labyrinth capsule, as clearly shown by the preparation, had a tendency to press the fenestra ovale outwards, which would rather tend to fix it in the extracted position and damage rather than improve the hearing. He quoted 22 cases of Blake, in Boston, who had operated in this direction with unsatisfactory results. If ankylosis have taken place extraction is impracticable. At the commencement of the morbid changes, when the characteristic symptoms have appeared, he usually prescribes large doses of the iodide of potassium, but with what benefit it is premature to estimate. Weichselbaum considered that the cases exhibited originated with inflammation of the mucous membrane, and eating deeper produced characteristic periostitis ossificans which was analogous to other bone formation. In chronic catarrh of the middle ear it was not unusual to find otseophyten. He thought there was no proof of any new formation of bone.

Prof. Gruber said that since 1890 he had always described this as otitis media hyperplastica, originating from the hyperæmia with subsequent hypertrophy of the mucous membrane and thickening of the bone. Such a new formation as understood by Politzer, he had never seen. The pathological change described by Weichselbaum is the most rational, as the fibrous tissue is often found to retrograde, and even atrophy of the tympanum, is often observed to follow. The spaces in the microscopic preparation by Politzer is a kind of porosity often occurring in atrophy of bone.

Politzer replied to this criticism that if the mucous membrane had been the primary locus in his cases there would be intensive changes in those parts and the bone itself which were absent. The changes were in the bone tissue and the primary source seemed to be the labyrinth capsule ; and even a thickening of the mucous membrane would not be opposed to the pathological changes in his cases.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Amputation of Both Mammæ.—Mr. Pearce Gould operated on a single woman, æt. 68, who presented a solid infiltrating tumour in the outer part of the left breast with one enlarged gland in the axilla, there were no adhesions to the skin and no retraction of the nipple ; in the right breast there was a smaller tumour in the sternal part which was also infiltrating and firm but without adhesions to the skin or pectoral muscle ; no enlarged glands could be felt in the axilla on this side. There was no enlargement of the liver nor evidence of deposits in either the lung or any internal organ. Both breasts were excised together with the fat and glands in the axillæ. In neither case was the wound for excising the breast prolonged into the axilla ; in one case the long axis of the incision was parallel with the pectoral muscle ; in the other it was horizontal. The wound was sutured without drainage and the dressings fixed with strapping passed across the front and sides of the chest, the arms being fixed to the side by a towel passed circularly round. Mr. Gould said that the tumours were undoubtedly malignant, but the evidence all pointed to the disease being primary in each mamma, and it was this which decided him to remove both breasts ; the question, he remarked, then arose as to whether this should be done at one or two operations, and the reasons for which he preferred to remove both at one operation were : 1st, the advantage of one anæsthesia ; 2nd, the shorter confinement to bed ; 3rd, the fact that the patient was very depressed on account of the nature of her disease, and it was feared that the psychical disturbance of the two operations might be more serious than the prolongation of a single operation and the greater physical disturbance caused by the removal of both breasts at once. On the other hand he pointed out that the reasons which might be urged against this course were the greater risk from shock and the discomfort of increased embarrassment to respiration caused by fixing both arms to the side. He drew attention to the ease with which the axilla is cleared out through the wound made for the removal of the breast, and the advantage of not prolonging the wound into the axilla as it is then more easy to keep aseptic.

It is satisfactory to state that the patient left the hospital the twelfth day after the operation perfectly well.

Strangulated Hernia through the Abdominal Wall.—The same surgeon operated on a man, æt. about 56, who had been admitted with an ovoid, smooth, firm tumour in the left side of the abdomen ; the long axis of the swelling was obliquely downwards and inwards, the centre of it being on a level with the iliac crest. There were signs of intestinal obstruction : vomiting not, however, fæcal, and constipation, no flatus being passed. Mr. Gould cut down on the tumour, and, after dividing the transversalis muscle, exposed the tense sac of a hernia which he opened, finding it to contain a congested loop of small intestine. He then divided the neck of the sac upwards, reduced the bowel, fixed the sac, tied it in two loops of silk, and cut it off. The opening in the abdominal parietes was carefully sutured layer by layer with buried stitches, and the skin wound closed in the usual way. The opening through which the hernia had escaped was in or near the linea semilunaris, and some distance above the inguinal canal. Mr. Gould referred to the extreme rarity of hernia in this situation apart from injuries, cicatrices or abscesses of the belly wall, all of which causes had been absent in the present case.

THE CANCER HOSPITAL.

Double Oophorectomy.—Mr. Bowreman Jessett operated on a woman, æt. 40, a widow, who, for the last eighteen months, had suffered from excessive hæmorrhage, coming on every three weeks, and lasting eight or nine days. The patient was much blanched. A fortnight ago a thorough examination had revealed a large intra-mural polyp in the posterior wall of the uterus. He said he thought the best thing to give the patient a chance of health was the removal of the ovaries and tubes. The front part of the operating table having been raised by an ingenious wooden support under the front legs, so that the patient's head was considerably lower than her feet (this Mr. Jessett considers to be of great importance in such an operation, as it causes the intestines to gravitate towards the diaphragm) an incision three inches long was made in the middle line, the ovaries taken up and the tubes ligatured close to the uterus, which was about the size of a large cocoa-nut. Mr. Jesset commented on the intense bleeding, and the great loss of flesh, and the discovery of a fibroid in the walls of the uterus, and said it was a question either of hysterectomy or of bringing about the menopause by the removal of the appendages.

Excision of the Rectum.—The same surgeon performed excision of the rectum on a woman, æt. about 40. The operation was undertaken on account of carcinoma of the bowel, extending nearly all round, forming a nearly complete ring about two inches from the anus. With the forefinger of the left hand in the rectum Mr. Jessett plunged a sharp-pointed knife into the tissues round the coccyx bringing the point out by his finger in the bowel and then cutting outwards ; next, with the finger still in the bowel, he freed the latter all round with scissors until he got beyond the disease, each vessel when divided being at once seized with Spencer Wells' forceps ; he divided the bowel in its healthy portion above the carcinoma, catching the edges of the circumference as they were divided in three or four pairs of forceps. The peritoneum was unavoidably opened, as the extent of the disease necessitated the freeing of the bowel for a considerable distance; the serous membrane was carefully stitched down with catgut to the covering of the anterior part of the bowel and the divided circumference of the rectum attached with chromic gut to the edges of the wound where the anus had been, the posterior incision being accurately brought together. A rubber tube without lateral openings was left in the bowel, this tube coming through all the dressings.

WEDNESDAY, JUNE 20, 1894.

THYROID GLAND IN SKIN DISEASES.

WHEN the history of modern therapeutics comes to be formally written, its pages will contain many curious records. It will tell of the rise of new methods and of new drugs, many of which, like the old-fashioned tar-water, ptisans, or the latter-day suspension treatment for locomotor ataxy, are destined to sink rapidly and for ever beneath the professional horizon. Here and there, however, the historian will write of discoveries that have made good their claim to a place in the armamentarium of the scientific practitioner of medicine. Among the sound and permanent additions to our therapeutic knowledge there seems to be every likelihood that the treatment of skin diseases by thyroid gland will, in no distant future, be included. One of the principal features of the Newcastle meeting of the British Medical Association last year was the announcement by Dr. Byrom Bramwell of the cure of certain cutaneous maladies by thyroid feeding. He had been led to make the experiment by noticing the marked influence on skin nutrition which the gland exerted on patients suffering from myxœdema. On proceeding to test the theory thus suggested on a number of cases of psoriasis, he was rewarded with a series of extraordinary results. This communication naturally attracted a good deal of attention on the part of the specialists to whom it was read. Many experiments upon all kinds of cases were undertaken in different parts of the country. The results seem to have been somewhat disappointing, however, that is to say, if we are to judge from published papers and reports of meetings. The general feeling, so far as one can gather, was that in thyroid gland the dermatologist found a powerful but erratic drug, which in some cases only was beneficial, or even curative. This attitude of reaction and doubt, however, has been seriously disturbed by Dr. Byrom Bramwell, in a paper read at the late Congress of the Dermatological Society. The observer in question brought forward a number of additional facts, which he handled in a scientific and logical manner. He was able to announce certain definite conclusions with regard to the drug, for instance, that it should be pushed to "Thyroidism," a state characterised by such symptoms as quick pulse, cerebral disturbance, and high temperature. Instead of prescribing one or two five-grain tabloids daily, it has been boldly administered up to 30 or 40 such tabloids in the 24 hours. The best results still appear to be obtained in the treatment of that curiously distinctive malady, psoriasis. In some cases the improvement is marked and immediate, with considerable scaling and rapid clearing up of the patches. Dermatologists who have used the remedy in psoriasis have been discouraged by the appearance of fresh crops of spots, but these, according to Dr. Bramwell, may be looked for and merely run an abortive course. The same observer *mirabile dictu*, has found that for a time the drug has a beneficial effect upon lupus, although later on cases relapse and the disease spreads; these bad results are attributable to what may be described as a kind of "chronic thyroidism." He has also reported a striking improvement in a typical case of ichthyosis treated by thyroid gland. Indeed, there can be little doubt that we are on the verge of a new world of therapeutics, the possibilities of which are many and various. As regards the particular instance under consideration, it is interesting to note the chain of events which has led to such unexpected results as the cure of psoriasis and other diseases by the administration of fragments of uncooked sheep gland. The first step was the careful description of the hitherto unrecognised condition of myxœdema, which was followed some years later by the extraordinary observation that the disease was curable by the use of sheep's thyroid either as an extract, or in a dried form. But these two triumphs of human intellect, the recognition of an obscure disease and the discovery of its equally mysterious antidote, have led to collateral results that are full of promise of a brilliant future. A general physician, struck by the subordinate effect of the gland on skin nutrition, was led to try its effect on certain well-defined cutaneous maladies. It is not too much to say that his experiment bids fair to open up issues that may profoundly modify the future treatment not only of special, but of general diseases. At the least, the facts he has advanced must considerably affect the attitude of dermatologists with regard to the constitutional origin or modification of pathological cutaneous conditions. The evolution of the series of events which has culminated in Dr. Bramwell's paper affords a marked instance of the well-nigh universal application that is possible to a well-ascertained fact. Curiously enough this discovery, which is so intimately concerned with the therapeutics of skin diseases, has been made by a general physician, as distinct from a specialist. This fact alone would justify the existence of the new Society of Dermatology for Great Britain and Ireland, which invites the active co-operation of all medical men who are interested in the study of its special branch of medical science.

A PROBLEM IN SEQUELÆ.

It is never an easy task to decide on grounds which shall resist the inquiring critic what is the exact relationship between particular morbid phenomena and a previous attack of a given acute disease. The difficulty is intensified when the malady is one with which we are, pathologically speaking, comparatively unfamiliar, such as influenza, or when a more or less considerable interval of time separates the disease from its sequelæ. It can, indeed, only be by prolonged and conscientious observation and the careful collation of results that the existence of any causal or predisposing relationship can ever be peremptorily established. This is a century of exact observation, and this is doubtless the reason why associations which our professional forefathers never even dreamed of are now generally recognised to exist. Take syphilis for example. If one turns to the most authoritative treatises on diseases of the nervous system, as recently as the time of Dr. Abercrombie, syphilis is not even mentioned, its influence on the production of disorganisation of the nervous system not having as yet been suspected, or, at any rate, not proved. In fact, authorities in this department showed the greatest reluctance to credit and accept the view of the distant effects of syphilis on the nervous system, though, at present, they are few who question the existence of this causal, though possibly remote, relationship. It is worthy of notice, moreover, that our knowledge of the distant sequelæ of most acute diseases is of quite recent date, and the more remote the connection, the longer, of course, has it taken to place the association on a sound scientific basis. These reflections are suggested by the discussion initiated by Dr. Sansom at the last meeting of the Royal Medical and Chirurgical Society on certain complications and sequelæ of influenza. Now, although records of influenza exist as far back as the thirteenth century, it does not seem to have occurred to anyone, previously to the last epidemic, that it had any particular sequelæ. Since the last great epidemic wave there has, on the other hand, been a plethora of such complications and sequelæ. There is hardly a disease under the sun which has not been described as occurring in the wake of an attack of influenza, but there is every reason to suspect that in a great many instances the association was fortuitous and not consequential. Even when the secondary phenomena occur in immediate relationship to the attack of influenza it is not easy to demonstrate their dependence on the previous illness, and when the interval is one of months or years the difficulty is, for the time being, insuperable. One can sympathise with the critic who said that he had long since ceased to take note of the history of a previous attack of influenza simply because it was of such common occurrence. This, however, is a dangerous course from a scientific point of view, for one incurs the risk of shutting one's eyes to an association which may positively be too obvious to be visible. Dr. Sansom has collected notes of a series of cases in which pain at the heart or morbid acceleration of the heart-beat had been manifested after influenza, and he promulgates the view that the initial cause was a disturbance of the vagus at its origin, or in some parts of its course, resulting from the action of the influenzal poison. He cannot truthfully be said to have placed his arguments on an irrefragable basis because, as we have already pointed out, such a demonstration can only be afforded by long and painstaking observation, bearing on a large number of cases. It must be shown that the symptoms were such as do not occur in any other association, in other words, we must be provided with some means of distinguishing cases which are due to influenza from those which merely occupy a subsequent position in point of date. There does seem reason to believe that influenza tends to set up peripheral neuritis in various parts of the body, in common with most acute specific disorders, but beyond this it would not, for the present, be safe to venture. It is all very well to suggest that the symptoms can be explained on the assumption of lesions situated in the medulla, but we are justified in maintaining an attitude of prudent scepticism towards assumptions which are not based on the results of post-mortem observations. It is so easy to assume and so difficult to prove, and the moment we leave the domain of actual observation the scientific horse takes the bit in its teeth and, to employ a colloquial expression, we do not know where we are.

THE ARMY MEDICAL SERVICES AND COMBATANT TITLES.

When the officers of the Army Medical Staff, both at home and abroad, first put forward the demand that their rank should be indicated by their titles, as is the case in every other branch of the service, everyone saw the justice of the claim, and it was granted to the fullest extent, notwithstanding the opposing jealousies of the heads of departments and leaders of the combatant service. The chief objection advanced by these was that if the "doctors" were granted these titles, there would be no stopping their further demands; that they would insist upon command and military authority appertaining to their rank, and would eventually claim to carry military titles without any indication that the titles were also medical

These forecasts, we are glad to say, have proved illusory in the great majority of cases. Members of the Army Medical Staff almost universally were content with their titles of Surgeon-Major, Surgeon-Colonel, and so forth, and with the acknowledgment of rank thus secured to them. But we regret to note that there remains a residuum of medical officers who yearn to be thought military and nothing more, and the vanity of these people maintains a state of ill-feeling between the combatant and medical services which we had hoped would have passed away. An officer who has this idea tries by all means to ignore and conceal his medical function. His visiting card describes him as "Lieutenant-Colonel Jones," the addendum "Army Medical Staff" being packed away in a remote corner in the smallest possible type, and when he goes out to dinner he desires himself to be announced as "Colonel Jones," and thus surreptitiously receives from strangers that homage which is dear to his poor petty soul. We have in our mind's eye one retired medical officer who has lived in a suburban district as "Colonel Blank," and has so successfully masqueraded in his military feathers that all persons —even the vicar of the parish—accepted him as a distinguished combatant officer, and were proportionately civil to him. We receive now and then letters from officers with this craze, begging us to agitate for new methods of expression and new rules which will make them a little like combatants. We shall do nothing of the sort. If these members of our profession are so ashamed of it that they prefer the ignoble position of hangers-on to the combatants, we are not surprised that the combatants treat them with merited contempt, and we shall not help them out of their humiliation. They should recollect that they are supposed to possess, in addition to the general education and the special military education which combatants possess, further scientific and professional attainments, which ought to make them regard themselves as the superiors of their military brethren. Their anxiety to hide away their medical function is an insult to their cloth.

◆

Notes on Current Topics.

Cycling as a Remedy for Obesity.

Among the reasons which determine persons over thirty years of age, and even under, to take to cycling, the desire to 'take down their fat," which is becoming a burden to them, is certainly a fairly common one. One is often puzzled to account for the appearance on wheels of persons, both male and female, whose build would seem to indicate an unfitness for this particular variety of exercise, and in many instances inquiry, if successful, will elicit the admission that it has been resorted to for the express purpose of getting rid of superfluous "flesh." Now in a certain proportion of instances the treatment of obesity by cycle exercise proves disappointing, and the explanation of this phenomenon presents a certain physiological interest. In the case of a healthy man, of fairly active habits, but who eats more than he can consume, cycling exercise, prudently indulged in, will usually bring down the body weight to the normal standard for the individual—this standard of course varying with each individual. It is otherwise, however, with stout females, who eat sparingly as a rule, and take a minimum of exercise of any kind. The tissues of such women are flabby, wanting in tone, and "watery," that is to say, infiltrated with a loose fat, giving rise to prominences which, on movement, remind one of "a reed shaken by the wind." The result of cycling exercise in these subjects is to improve the tone of the tissues, to stimulate the appetite, and ultimately to bring about the substitution of firm, physiologically healthy tissues for the atonic structures which formerly did sorry duty for them. Far from procuring any diminution of weight, a positive gain may result, this time *up* to instead of *down* to, the normal body weight. However æsthetically objectionable this may be, it is, from a physiological point of view, the best thing that can happen. The highest standard of health is attained in the individual only in presence of a normal body weight, and any departure from this standard in either direction is *pro tanto* a departure from the ideal standard of health. Let the fair ones console themselves for the gain in weight by the enhanced zest thus given to mere existence. Stoutness due to fat is literally a burden, but stoutness due to muscular development is, or may be made, the guarantee of a healthy and enjoyable existence.

The Eating of Wall-Paper.

A most amusing essay in amateur medicine is now going the round of the newspapers. It professes to account for what we are told is a "strange but common habit" among children, namely, that of tearing away wall-paper and eating off the mortar underneath. This information, if we mistake not, will be fresh to most of our readers, as well as the following explanation:—"Lime is an absolute *sine quâ non* to children who are bone-making, and yet cheap and common as it is the children of the London poor are often unable to obtain it. Driven by their unfailing instinct, they will, if so desired, eat anything, let it be ever so objectionable, if only it happens to contain the materials for bone-making. I have seen a whole group standing around a hole in the wall of a London cottage and eating the mortar, and amused myself and the mother by placing a pail of water, into which a piece of lime had been secretly dissolved, in one corner of the room. The children, without other guidance than instinct, will, in the course of an hour or two, find this lime-water, and drink of it with great regularity. Thenceforth no amount of scolding will induce them to go back to the hole in the wall." The writer of this curious production evidently has no knowledge of the widespread distribution of lime salts in food stuffs. Both bread and milk contain lime, which is present to an enormous extent in many potable waters, notably in that supplied to Londoners. The science of medicine may be, as the author asserts, an empyric (*sic*) thing, but we must altogether dissent from his proposition that "taste is the unerring voice of Nature telling the child what is best for it." It is a well-known fact that the appetite of children is omnivorous; but it seems an unkind theory that Providence inspires the child with a desire for marbles, coal, boiling water from kettles, paint, or any other indigestible provender of any kind whatever that may be within reach. The ingenuity and powers of observation shown by the author of this theory are obviously handicapped by the absence of logical method in the examination of his arguments.

The Fatal Poisoning of Sewer Men.

The inquiry into the recent death from poisoning of two sewer men has revealed the fact that the men were asphyxiated with sulphuretted hydrogen. It was alleged by the Lambeth Vestry authorities that the gas was generated from a large quantity of sulphuric acid which had been allowed to flow into the sewer from an oil refinery, a statement, however, which was strenuously denied by the firm to which the refinery belonged. The curious fact, however, was testified to by Dr. Stevenson, the analyst to the Home Office, namely, that the metropolis was the only part of England where waste chemicals and hot liquids above 120°F. were permitted to be run into the sewers. This danger has been fully recognised in other parts of the United Kingdom, and it is prohibited by statute. But if the sewers are kept properly clean, presumably it would scarcely matter much what the character of the liquids was which flowed into them. On the other hand, supposing the sewers are allowed to remain in a foul condition, obviously any powerful chemical reagent, such as sulphuric acid, would be certain to be productive of harmful results to the men. The matter, of course, is one of great moment; so much so that it seems to call for an exhaustive inquiry by the authorities who control this department of the metropolis. The jury laid a good deal of stress on the important evidence which was brought before them, and in their verdict attributed the deaths of the men to the wretched state of the sewers, and the foul gases arising therefrom, while, in a rider, they censured the parish authorities for their careless supervision of the sewer. We trust that the attention which has been drawn to this matter will be productive of good results.

The Coming Election to the Council of the Royal College of Surgeons of England.

We regret to have to state that, owing to a mistake in the date for forwarding to the College his application as a candidate for the Council, Mr. A. T. Norton will not be able to take part in the contest on the 5th prox. This untoward event is all the more to be regretted inasmuch as the election will thus be deprived of most of the interest with which it would otherwise have been surrounded. Mr. Norton had been adopted as the candidate of the Association of Fellows, and no stone would have been left unturned to effect his success at the poll. He would have been, in truth, the only candidate openly pledged to secure those much-needed reforms in the government and constitution of the College in connection with which the Association of Fellows has shown itself to be a working body of so much utility to the Fellows generally. The candidates who are now on the list for election to the three vacancies are: Mr. Reginald Harrison, Mr. Howard Marsh, Mr. Hardie (of Manchester), Mr. Davies-Colley, and Mr. Page. In view, however, of the Association of Fellows having no candidate specially nominated to represent the reform movement among the Fellows, it becomes an essential matter to consider who those candidates will be whom the Association will decide to support. Hazarding a guess, quite likely the decision will be arrived at to favour the return of Messrs. Harrison and Marsh, as the retiring Councillors, and Mr. Davies-Colley—who, although avowedly a member of a clique which has been started to oppose the Association, has, nevertheless, taken no active part in that opposition. With regard to the other two, Messrs. Hardie and Page, it need only be said that they have both been prominent in forming that society whose object is to undermine the good influence of the reforming section of the Fellows.

The Teaching of Surgery.

Two papers of some note, both on the subject of the teaching of surgery, were read at the meeting of the American Surgical Association, held at Washington last month. The first was a contribution from John S. Billings, and the second by Dr. John Chiene, of Edinburgh. The latter based his observations upon the following proposition, namely, that the teaching of surgery resolved itself into two divisions. First, systematic consideration of general principles, illustrated by clinical examples. Secondly, a clinical (bedside) opportunity given to observe, to use, and to educate all the faculties, physical and psychical. Under either head the teacher must be a learner, the student a teacher. The practice of surgery to be successful must be dogmatic. Attention is drawn to the fact that now that we have books, something may be said for the objection that no systematic lectures are required; indeed, it has been asserted that there is no need for a hundred lectures on any subject. But experience amply proves that speech is a great stimulus to the diffusion of knowledge, and however valuable books may be as an integral part of an educational system, they can never supersede the personal, so to speak, method of imparting knowledge comprised in the delivery of lecturers.

The Plague at Hong Kong.

The island of Hong Kong has been suffering from the ravages of a terrible epidemic. Its inhabitants are mainly Chinese, with about two hundred Europeans. Since the first outbreak of the disease on May 4th no less than 1,900 Chinese have died, but hitherto the Europeans, with the exception of ten British soldiers, have been free from attack. There can be no doubt that the epidemic is the true Oriental plague, answering to the terrible pestilence which ravaged Europe in the Middle Ages. The invasion is rapid, and the disease is marked by fever, bubo, typhoid symptoms, great prostration, and in most cases rapid death. Hong Kong, for all its extreme beauty, is an unhealthy place, especially in the densely-crowded Chinese quarters. Its importance as one of the two great commercial gates of China can hardly be exaggerated. It is a vast commercial centre, and the present unfortunate visitation can hardly fail to be disastrous to the Chinese trade. Unfortunately there is considerable danger that the disease will be conveyed to Shanghai. The moral of the situation is obvious, namely, that the British Government will have to enforce absolute sanitary measures in the island of Hong Kong. Short of that proceeding there can be no safety in a country where wholesale poisoning of earth, air, and water is the rule, and cleanliness of any kind the exception. The plague has been driven out of Europe, but has survived in China, doubtless due to the filthy habits of the people. The free inter-communication that goes on between China and Hong Kong must necessarily expose the latter to the constant risk of the introduction of cholera and other epidemic diseases. The future safety of Hong Kong must be ensured by a rigorous quarantine of immigrants and the institution of a thorough system of sanitation. Already suggestions are afloat to destroy the Chinese native quarter of Hong Kong by fire; but if this is carried out the latter threaten destruction with the same element of the British settlement at Shameen.

Small-Pox amongst Tramps.

The fact that small-pox is often spread by tramps has of late been again and again forcibly demonstrated. Seldom, however, has the moral been pointed in a more disgraceful manner than in a late occurrence at Rawtenstall. It appears that there is a sordid dispute going on between the Corporation and the Guardians as to which shall bear the cost of cases sent to the fever hospital. On a certain Monday evening a case of small-pox was reported in a Rawtenstall lodging-house containing some forty or fifty inmates. The patient, however, was allowed to remain where he was until Tuesday evening, when he was given an overseer's order and sent to the infirmary. On being refused admission at the latter place, he is stated to have paid a visit to a public-house, and then to have gone on to Newchurch, where he spent another night in a lodging-house. Next day he went to Burnley, and there he was at once placed in an infectious hospital. The Rawtenstall authorities are likely to have a practical lesson in economics, for there is every chance of their having to deal with an extensive outbreak of small-pox as a result of their "penny wise and pound foolish" policy.

Marriage with a Deceased Wife's Sister.

This perennial source of physiological argument *versus* sacerdotal principle, in the shape of a Bill in Parliament, has once again received its quietus, and we have received the usual, or rather more than the usual, number of letters from those of our readers who affect a desire to deal "fully and clearly" with the physiological aspect of the question. Now we are far from denying that marriage has a physiological aspect, and this whether the parties thereto are or are not within the objectionable limits of relationship. But the reiterated fate which has overtaken this particular Bill is not, we imagine, determined by or on physiological principles, and it is consequently useless to discuss problems which are, after all, not germane to the subject. The time may come when the Government will refer the matter to the *to be-created* Academy of Medicine of Great Britain, and then will be the time for our correspondents to forward their essays on the physiology of marriage between and within certain affinities.

Prosecution of Chemists.

The tactics of retaliation of the Patent Medicine Vendors' Association have certainly a humorous side, even if those tradesmen against whom the manœuvres are directed are made to suffer. At Oldham last week no less than eight chemists were summoned for selling a syrup containing some scheduled poison without entering the transaction in a book, and to a person unknown. The same offence was also made to include the sale of fly-papers, concerning which so much was heard during the trial of Mrs. Maybrick. No definite decision was arrived at, for the magistrates adjourned the case for a week, presumably to ascertain the law on the subject. Of course, if chemists do not wish to be subjected to vexatious actions of this kind they must comply with the law. At all events, it is to be trusted that this species of retaliation will have no effect upon the policy of the Council of the Pharmaceutical Society, which has been carried out with so much benefit to the public in the prosecution of vendors of quack-medicine.

Anti-Vaccination at Trinity Hall, Cambridge.

Broadly speaking, the ranks of the anti-vaccinators are recruited from the less educated classes of society. Men of cultured understanding are usually content to form their opinions on such technical scientific matters upon the principles accepted by the authorities on such subjects. Much learning, however, is by no means the invariable hall-mark of wisdom, a fact which is shown by a little anti-vaccination incident that has lately taken place at Cambridge. A Mr. Bell, described as an assistant tutor of Trinity Hall, was summoned to the police-court of that town for non-compliance with a vaccination order. His defence was of a novel and ingenious nature. He contended that vaccination was inoculation, and by section 32 of the Act of 1867 anyone is liable to one month's imprisonment for inoculation. The magistrate remarked that, according to that argument, every medical man who performed vaccination would be liable to imprisonment. The assistant tutor, we are glad to observe, was fined for his attempted evasion of the law.

A woman doctor has been appointed on the medical staff of the Lancaster County Lunatic Asylum. A large number of female lunatics are confined in the asylum.

Elephantine Surgery.

Veterinary surgery is a matter of increasing interest and importance, and, according to the newspapers, has lately been raised to an unexpected degree of refinement. It is reported that a Parisian dentist has recently filled a considerable gap in the tooth of a performing elephant engaged at the Nouveau Cirque. For a long time the poor beast had suffered agonies from toothache, due to molar caries. This was diagnosed by Professor Valadon, who proceeded to drill out a cavity three inches deep by the aid of his largest instruments. The hole thus made was stuffed with iodoform cotton for some months, and then filled with composition cased in with a tin cylinder. During the operation the sagacious beast remained perfectly passive, being evidently aware that the object of the surgeon was to relieve him from suffering. The director of the circus was anxious to have the tooth filled with gold, but decided on the composition when he heard that £60 worth of gold would be required for the purpose! Diseases of the teeth are not uncommon among elephants in a state of captivity. Some of our readers may recall the fact that the celebrated elephant Tippoo, which was shot because it was supposed to have gone mad, was found *post mortem* to have a large abscess at the root of a molar tooth.

Lady Medicals in Scotland.

In Edinburgh, for the time at least, a peace has been patched up between the advocates and opponents of the medical education of women and the attendance of female students at the infirmary wards set apart for their use grows larger continuously. In Dundee, however, the cause is not on such a satisfactory footing, as the managers of the Royal Infirmary there have just refused to allow female students into the institution. There may be circumstances in the way about which we know nothing, such as the impossibility of avoiding mixed cliniques, or inability to set apart a sufficient number of beds for the women; but in these latter days, when the lady student is ubiquitous, it savours somewhat of obstinacy to endeavour to keep her out of a teaching hospital altogether. Already eight qualified lady doctors are practising in Edinburgh, and two in Dundee, while we believe the number in Glasgow is very much larger.

The Forthcoming Report of the Vaccination Commission.

We learn that the labours of the Vaccination Commission are approaching completion. At the last meeting, held a couple of months ago, the Secretary was instructed to obtain information upon certain points arising out of evidence admitted at the last moment. This information is now ready to be submitted to the Commissioners, who will accordingly be able to commence the consideration of their report without delay. The prospect of unanimity in connection with the Commissioners' recommendations is remote, and, whatever may be the general tenour of the report, a separate document is certain to be drawn up by the minority. Undeniably regret will generally be felt if, as is here suggested, the report does not prove to be a unanimous one; but, after all, whatever the ending of this matter may be, one thing is certain, namely, that the anti-vaccinationists will have to remain satisfied for a long time to come with the free ventilation of their grievances afforded them by the Commission.

The Nursing Staff in Bath Workhouse Infirmary.

Notwithstanding the publicity which has been given to the scandalous state of the nursing in the Workhouse Infirmary, the Bath Guardians seem disinclined to take any steps to remedy matters. Mr Craddock, the Medical Officer, lately wrote another strong letter on the subject, but receiving no satisfactory answer, he has sent in a report to the Local Government Board. Amongst a batch of other interesting facts he communicates the following. "In Ward No. 148 there were, last week, eleven children, two of them cases of pneumonia. On Thursday last they were both exceedingly ill, and likely to die. In charge of this ward were two pauper women, aged respectively 69 and 75 years. Between my visits on Thursday and Friday one child died, and as I entered the ward on the morning of the latter day, these old women were dusting the ward; but, to my horror, I saw my other little pneumonic patient sittng up in bed near an open window with the wind blowing in upon him, and the rash of measles well out." It is to be hoped that the Local Government Board will at once put an end to this intolerable state of affairs.

The Ophthalmic Department at St. Bartholomew's Hospital.

We understand that a vacancy will shortly occur in the Ophthalmic Department of St. Bartholomew's Hospital, owing to the resignation of Mr. Henry Power, Senior Ophthalmic Surgeon and Lecturer on Ophthalmic Medicine and Surgery at the Hospital. Mr. Power was appointed in the year 1870 to the post which he is now about to resign, when the ophthalmic wards were built, and we believe it is a fact that, among the large general hospitals, St. Bartholomew's was the first to open a special department for the treatment of diseases of the eye, and place it in charge of a surgeon who confined himself to that speciality. Mr. Bowater Vernon was at the same time appointed as Mr. Power's colleague, and will presumably now succeed to the vacancy created by the resignation. The promotion of Mr. Vernon will leave a vacancy for a junior ophthalmic surgeon, and for this appointment quite possibly there will be much competition.

The Public Health Committee of the London County Council have decided to convene a Conference of urban sanitary authorities, to be held next month at Spring Gardens, to consider whether any measures can be taken to restrict vagrants as agents in the spread of small-pox and other infectious diseases.

The Power of Re-Vaccination.

The *Star*, the *Echo*, and the *Daily Chronicle*, the three newspapers in London which fatten upon the notoriety they have gained from their opposition to vivisection and vaccination, are at present engaged in endeavouring to belittle the good effects of re-vaccination. Of course, it is quite impossible to say anything which would ever be likely to convince a faddist that his fad is merely a delusion. For facts and figures the average faddist displays the greatest scorn; all those figures and facts, for example, which do not bear out his propositions, or agree with his conclusion, are cast aside and ignominously avoided. Nor is it the rule for any effort to be made by the faddist to refute them —he adopts the sage course of leaving them severely alone and refuses to be convinced, even when common sense would suggest that conviction was unavoidable. In the midst of the libellous statements against re-vaccination which have been propagated, it is well that some authoritative facts should be disseminated in which the truth of the matter is plainly displayed. The Vestry of St. Mary, Islington, therefore, has done good service by the issue of a small pamphlet entitled "A Few Facts about Small-pox, Vaccination, and Re-Vaccination," compiled by their Medical Officer of Health. So far as re-vaccination is concerned, he points out that in the London Small-Pox Hospital an experience of fifty years has proved that the protection of re-vaccination is so great that nurses, who must of necessity be in the closest proximity to the disease, were never infected. Again, in the Metropolitan Asylums Board Hospitals, out of 734 nurses and attendants, 79 who had previously been attacked with small-pox, together with 645 who had been re-vaccinated before entering upon their duties, escaped the disease, but the remaining ten had not been re-vaccinated, and every one of them contracted it. Lastly, from 1876-79, in London, out of nearly twelve thousand patients admitted into the small-pox hospitals, no case of small-pox was known of any person who had been efficiently vaccinated, and successfully re-vaccinated.

State Surgery.

Just as we are rejoicing over the recovery of our veteran statesman, Mr. Gladstone, from a successful operation for cataract, we learn that M. Jules Simon, the well-known French politician and ex-Minister, has had to undergo the operation of iridectomy at the hands of Dr. Landolt, the eminent Parisian oculist. This, we are informed, is only preliminary to an operation for cataract, which it is proposed to perform in October. The procedure was so far successful that M. Simon was enabled to contribute his weekly article to the *Figaro* as usual, and we trust that the subsequent steps may prove equally satisfactory.

The very alarming outbreak of eight cases of small-pox in the North Dublin Union, which was transferred to the Hardwicke Hospital, has fortunately, owing to the decision of Sir Charles Cameron and the hospital authorities passed away. There has been no death, though one of the cases was of the most confluent type. Within the last few days one other case has been admitted to the Hardwicke, but it is not expected that the epidemic will go further.

The scales of medicines, medical stores, and instruments for merchant vessels, prepared under the provisions of the Merchant Shipping Act, 1867, have just been revised by the Board of Trade. Separate medical scales for merchant ships, for North Atlantic steamships, and for passenger ships have been prepared.

On behalf af the building fund of the Dental Hospital of London, Leicester Square, an exhibition of pictures by prominent artists is to be held from June 25th to Monday, July 2nd, in the Royal Institute of Painters in Water Colours, Princes Hall, Piccadilly.

Special Articles.

THE ANTWERP EXHIBITION.

[From our Special Reporter.]

II.—The Sanitary Sections.

Continental cities for the most part present a curious contrast to our own, they are generally outwardly far more clean and orderly than ours, but when one comes to inquire into sanitary arrangements, grave defects are revealed. Antwerp is a bright, clean-looking town, with well swept streets and handsome houses, nevertheless, its sewerage is decidedly of the most primitive description. Cesspools are the rule, and sewage is carted and barged away to the sea. In one corner of the Exhibition the town of Antwerp makes an instructive display of such arrangements as come under the supervision of of the Municipal engineer and the medical officers. This collection of models and photographs at once betrays the weak spot in the civic sanitary armour. There are models of the huge reservoirs on wheels, with pneumatic pumps, employed for emptying the cesspools in almost every quarter of the town. There are two shifts of service, for night and day work. The contents are emptied into gas tight iron barges, which lie in the canals near to the Municipal Depôts. The sewage is for the most part barged out to sea and deposited there. As far as they go, these machines, as represented by the models on exhibition, are perfect, their working being nearly automatic, and every precaution being taken against leakage or the escape of sewage gas. But the weak point is very weak indeed. In many of the tall houses in the old town, soil-pipes run straight up from the cesspools to the top of the house, no traps being used, and no water. The consequence is that the cesspools are effectually ventilated into the warm houses. Were it not for the constant use of the pneumatic emptying engines, the sanitary condition of the town would be far worse than it is. There are also models of dust and rubbish carts. These are of excellent pattern and might well be copied by some of our British Vestries and civic authorities. The carts are made of galvanised iron sheets, strongly rivetted, in wood frames. The covers, also in galvanised iron, swing back on protected hinges, and have metal wings to prevent the scattering of dust; they are tip-carts. Wheelbarrows built on the same principle are used for cleaning the streets, this work being usually done by one man and a woman sweeper to each wheelbarrow. For the new quarters of the town mechanical road scrapers and brooms are used. Steam disinfectors are used for house purification after contagious diseases. Several firms exhibit sanitary apparatus in metal, galvanised or enamelled, pottery, &c. Among these we may mention Twyford, of Hanley, whose specialities of water closets, drainage tubes, and other articles, in enamelled fire-clay are of high value; the enamelled baths, syphons, &c., &c., manufactured by the Co-operative establishment known as the Société du Familistère, of Laeken, Belgium, whose enamel is of good colour and excellent quality, and various appliances in Belgian pottery ware. These last are not remarkable, the Belgian clay-workers, so far as regards building and sanitary appliances, making a poor show. Steam disinfecting apparatus and washing machines are also shown, though in these classes there is nothing worthy of special notice, nothing to come up to various familiar British patents. Messrs. W. H. Wright & Co., of Brussels, show an excellent selection of British sanitary house appliances.

Among the curiosities of the Exhibition must be mentioned Captain C. J. Tackel's elaborate plans for the storage of water from two immense water-sheds, thus procuring an abundant supply of pure water for Brussels, Antwerp, and other towns. The worthy Captain also exhibits diagrams and particulars of a method for the purification of canals, &c. He constructs filter beds estimated to last for a century; the purification being accomplished by reaction and precipitation by the help of sulphate of protoxyde of iron, sulphate of iron, and sulphate of lime. The inventor declares he could purify the pestilential canals of Marseilles. If he could indeed do this work of sanitation for Marseilles and Hamburg, he would place the whole of Europe under the greatest obligation. Another curiosity is to be found in the German section; a house built of zinc blocks, and zinc plate moulded on wood. The structure is light, cleanly, and said to possess peculiar sanitary advantages.

M. Müllender showed plans for the extension of Antwerp to the left bank of the Scheldt, to relieve the conjestion of the old town, providing cottages, public gardens, &c. The improvements would cost several millions.

As regards the internal fitting of houses, some advance is shown in the matter of ventilation, which is often combined with a system of heating. This seems to be a battle ground for the opposing factions of open grates and closed stoves. Some useful patterns of stoves for hot air, steam, and hot water are shown. But in spite of the long experience of the Germans, apart from their enamelled stoneware stoves, they do not show any decided superiority over British manufacturers. The Government and Municipal schools exhibit interesting regulations for the teaching of hygiene and sanitation, and some of the industrial and technical schools show drawings and models of various apparatus and appliances.

A branch of sanitation strongly represented is that of apparel, though we must confess that the plain uniforms for boys in the military schools, and those in other schools as well as those especially designed for gymnastic exercise, more nearly approach the ideal than those specifically labelled "sanitary." A comparative new comer for honours is the "Poil de Bretagne," a so-called natural wool, subjected to certain patented manipulation; it is, however, soft and comfortable, and no doubt adapted for the manufacture of underclothing, &c. But in the matter of clothing the only way to hygienic results is by simplication, a process of doing without rather than adding to. A good word, however, must be said for the ingenious tent-waterproof coat exhibited by Isaac Maulner and Sohn, of Vienna. These tents are made in two sections of light but strong waterproof canvas. The tent is large enough for two soldiers or travellers, and when taken to pieces each section forms an ample wrap with flap hood and sleeves. They are warm and comfortable and keep off the wet. The sleeves form windsails or ventilators for the tents. Very simple framework is used, taking up little room in a haversack or on the top of a knapsack. A capital idea susceptible of wide application.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Proposed Scottish Local Government Board.—We are glad to see that the Scottish Grand Committee has resolved to give the Medical Officer of the proposed Board equal rank with the other members, a very necessary arrangement, as he will be able to take part in any discussions which may arise and give opinions which, from a member of the Board, will have more weight than from merely a subordinate official. It is to be hoped that the House of Commons will not overturn the decision of the Committee. Some speculation has already been excited in Scotland as to who will get the proposed post, and one or two names have been mentioned, of whom it would be unfair at present to speak.

The Small-pox Epidemic.—The number of cases of small-pox notified in Edinburgh during last week rose to 25, those in Leith to 20. Revaccination is being carried out very generally in both cities, medical professors and students alike vying with the general public in this direction. We heard of one firm of chemists alone selling over 2,000 tubes in the week.

Glasgow University General Council.—The Chancellor of the University, Lord Stair, has, on the requisition of a quorum of members, convened a special meeting of the Council, to be held on Tuesday, 26th inst. The principal business of the meeting will be the consideration of a number of draft ordinances recently issued by the Commission, in the case of which the three months allowed to the Council by the Universities Act for intimating objections or amendments will expire before the next half-yearly meeting of the Council. The ordinances to be discussed will include some of special interest to educationists, amongst the subjects dealt with being the encouragement of special study and research, higher degrees in arts and science, the qualifications of candidates for chairs, and the position of the General Council in regard to procedure at its meetings. The Business Committee have prepared a report on these subjects which will be issued to members shortly. The meeting being a special one, an attendance of sixty is needed to make a quorum.

The Emeute of Students at Glasgow University.—The daily riot in the Medical Jurisprudence Class-room in the University has assumed such proportions that Principal Caird has had to interfere on the score of law and order, the cause of the disturbance being the unavoidable absence of Professor Simpson through illness necessitating the employment of a substitute to deliver the necessary lectures, the latter seeming not to be acceptable to the students. On the 14th inst. the Principal made his appearance in the class-room, receiving quite an ovation from the turbulent medicals. The Principal showed his tact by prefacing his scolding with an acknowledgment of the kindness of his reception. The reprimand was milder than was generally expected, and in general terms appealed to the "manliness and gentlemanly instincts of the students." The refining influence of Queen Margaret's students would seem to be somewhat tardy in coming into operation.

We understand that Professor Macewen, at his recent clinical examination, had his students confined in a room for so many hours that he had compassion on them and apologised for their enforced confinement by supplying them with tea and buns!

Hospital Sunday for the Three Glasgow Infirmaries.—We understand that the three Glasgow Presbyteries, representing about 300 churches, Archbishop Eyre, as representing the Roman Catholic churches, as well as the clergymen of most of the other denominations in the city and neighbourhood, have decided to have a simultaneous church-door collection for the infirmaries on Sunday, 28th October next. A large and influential committee has been formed, with the Lord Provost at its head as convener, with the view of carrying the project to a successful issue.

The General Board of Lunacy have resolved to investigate some charges made against the Medical Superintendent of Inverness Asylum, and have provisionally fixed Friday, the 22nd inst., for the inquiry.

Obituary.

DR. ROBERT JOLLY, OF BIRMINGHAM.

The death is announced of Dr. Robert Jolly, senior surgeon to the Birmingham General Hospital, and consulting surgeon to the Birmingham General Dispensary, the event occurring a few days since at Bournemouth, after a somewhat protracted illness. Deceased went to Birmingham from Edinburgh, where he took his degree of M.D. in 1862. He had been resident surgeon at the Edinburgh Royal Infirmary, and demonstrator of anatomy in the school of the Royal College of Surgeons. His first appointment in Birmingham was that of house surgeon at the Queen's Hospital. He subsequently became assistant surgeon at the General Hospital, an office which was shortly afterwards abolished, upon which he was, in 1870, admitted as full surgeon. In 1868 he was elected Fellow of the Royal College of Surgeons, Edinburgh, and shortly afterwards was appointed lecturer on anatomy at Queen's College, a post which he held for many yeaars. For years past, deceased had an extensive private practice, and for many years he held the office of police surgeon, in which his considerate treatment of the men caused him to become very popular among members of the force. Some months ago, Dr. Jolly was compelled to give up work by reason of the development of a severe form of kidney disease. He repaired to Bournemouth, and recently made so much improvement that he anticipated an early return to practice, and accepted election by his colleagues at the General Hospital as chairman for the year of the Medical Committee of the institution. His illness, however, took an unfavourable turn, and terminated fatally on the 9th inst.

MR. SAMUEL WM. NORTH, M.R.C.S., OF YORK.

By the death of Mr. North on Friday last, the city of York loses its Medical Officer of Health, and one of its most respected and popular citizens. Deceased was a man of large experience and diversified talents, and his opinion was frequently sought outside the pale of his profession. He was one of those who carried out literally the conviction, *mens sana in corpore sano*, and he became a member of the Medico-Psychological Society, and a Fellow of the Sanitary Institute. As Medical Officer of Health for the city in which he passed the greater part of his life, he was highly esteemed, and to his wise administration in this direction, the high position York now occupies for healthiness, much is undoubtedly due. Mr. North was also a vice-president of the Philosophical Society, a member of the Anthropological Institute of Great Britain and Ireland, and at the time of his death held the posts of Senior Surgeon to the York Dispensary, Surgeon to the York Union Workhouse, and Fever Hospital, and Medical Visitor to three lunatic asylums in Yorkshire. Mr. North obtained his M.R.C.S. diploma in 1852, and has contributed various papers to scientific and medical literature.

Medical Sickness, Annuity, and Life Assurance Society.

The expiration of the first decade in the history of this society finds, it what it never ceased to be from the beginning, a flourishing and highly successful undertaking. Thanks to an economy of management largely effected through the disinterested counsels of its founders, and of Mr. Ernest Hart in particular, less than half the usual rate of disbursement under managerial charges has been incurred, and this fund consequently shows a very substantial reserve to its credit. During the last twelve months, close on £4,500 has been paid in sickness and accident claims. and year by year the membership roll increases. One has only to inspect the annual reports to be made aware that the society has been the means of enabling many a practitioner to provide against misfortunes which, for being unexpected, have proved none the less disabling. We note a curiously large proportion of claims for accidents of late, many of them of a very serious nature, and the claims paid under this head more than compensate for the comparatively small amount of sickness. This is a form of incapacity against which the most robust health and the stoutest frame can afford no adequate protection, yet it is one which the medical practitioner, whether in town or country, is bound to face in the daily exercise of his profession. We are very pleased to bear this testimony to the continued success of a truly beneficent institution, and we trust this success will be maintained and exceeded in the future.

The Management of Chemists' Shops.

Referring to the judgment recently delivered in the Scotch Appeal Court, Edinburgh, in regard to the question of unqualified assistants in chemists' shops kept by medical men, the *Pharmaceutical Journal* remarks that it is now made clear that whether a chemist's shop be kept by a person qualified under the Pharmacy Act, or by a medical man in virtue of his exemption from that requirement, the retailing, compounding, and dispensing of poisons cannot lawfully be carried out by any but duly qualified persons. The exemption of the medical man enables him to keep open shop, and personally to sell, compound, and dispense poisons in recognition of his competence to perform these duties, but in carrying on the business of a chemist and druggist, he otherwise stands in exactly the same position as a person qualified under the Pharmacy Act.

Prosecutions under the Dentists Act.

The British Dental Association has instituted a series of prosecutions against certain persons for infringing the Dentists Act, 1878, by either holding themselves out as dentists or as being specially qualified to practice dentistry when, as a matter of fact, they were not registered, and held no legal qualifications. At Manchester, before Mr. Headham, the Stipendiary, James Macdonald, was fined £10 for using the expression, "Telegraphic address, 'Dentist, Manchester,'" in his advertisements, and £5 for describing his premises as a free dentorium, with £5 costs.—L'Estrange was fined, at the same court, £5 and costs for describing his premises as a dental surgery.—At Lancaster, before the justices, R. Knowles, a chemist, of Morecambe Bay, was fined £1 and costs, "as a warning to others," for holding himself out as being specially qualified to practise dentistry.

Vital Statistics.

The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 16·9 per 1,000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year, and were—Birkenhead 16, Birmingham 20, Blackburn 12, Bolton 16, Bradford 13, Brighton 13, Bristol 15, Burnley 17, Cardiff 13, Croydon 13, Derby 15, Dublin 21, Edinburgh 20, Gateshead 14, Glasgow 19, Halifax 19, Huddersfield 15, Hull 15, Leeds 16, Leicester 13, Liverpool 25, London 16, Manchester 17, Newcastle-on-Tyne 18, Norwich 13, Nottingham 14. Oldham 16, Plymouth 13, Portsmouth 9, Preston 20, Salford 20, Sheffield 17, Sunderland 18, Swansea 13, West Ham 15, Wolverhampton 14. The highest annual death-rates were—From measles, 1·6 in Nottingham, 2·0 in London, and 2·4 in West Ham; from whooping cough, 2·0 in Sheffield and 2·6 in Newcastle; and from diarrhœa, 1·1 in Swansea. The death-rates from scarlet fever and fever did not reach 1·0 per 1,000 in any of the towns.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

B. K.—We cannot offer any opinion with reference to the publication of the paper until it is submitted for inspection.

Mr. L. H. P.—No one who respects himself or his mother tongue would connive at the introduction of such a term as "Cowperitis" to designate an inflammatory condition of Cowper's glands. We regret that indifference or downright viciousness should have allowed this term to find a place in our literature, constituting as it does a philological misdemeanour of the first order.

EXHIBITIONS AT THE ROYAL MEDICAL BENEVOLENT COLLEGE.

An official notice will be found in our advertising columns of an examination for the admission of boys of the less fortunate members of the profession as "Council Exhibitioners." Candidates who are successful are boarded and educated at about half the fees charged for admission to ordinary pupils.

A Candidate.—The book is a very good one, but is not up to date in modern surgery.

M. C. V.—We have standing arrangements for work of the particular description to which you allude, and it could only be by chance that any occasion would arise for extraneous assistance.

Dr. M. P.—We prefer subscriptions to be paid in advance, but we do not insist upon it in every instance.

General Practitioner (London).—Your letter is unavoidably crowded out at press.

Meetings of Societies, Lectures, &c.

Wednesday, June 20th.

London Post-Graduate Course.—Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Syphilodermia.

Metropolitan Hospital (Kingsland Road, N.E.).—At 5 p.m., Dr. Risien Russell: Cerebral Localisation. (Post-Graduate Lecture.)

Royal College of Surgeons, England.—At 5 p.m., Prof. T. Pickering Pick: Diseases of the Ends of Long Bones in Children.

Royal Meteorological Society (25 Great George Street, Westminster).—At 8 p.m., Mr. Robert H. Scott: Fogs Reported with Strong Winds during the Fifteen Years 1876-1890 in the British Isles.—Mr. Richard H. Curtis: Some Characteristic Features of Gales and Strong Winds.

Royal Microscopical Society (20 Hanover Sq., W.).—At 8 p.m., On the Unreality of certain Characters generally accepted for Specific Diagnosis in the Diatomaceæ.—Mr. F. Chapman: Foraminifera of the Gault of Folkestone.

Thursday, June 21st.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street.—At 3.30 p.m., Mr. Bernard Pitts: Treatment of certain Acquired Deformities in Children. National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Taylor: Electrical Testing and Treatment. Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. Stanley Boyd: Cases in the Wards.

Friday, June 22nd.

London Hospital Medical College.—At 4 p.m., Mr. Jonathan Hutchinson: On Bazin's Malady.

Royal College of Surgeons, England.—At 5 p.m., Prof. T. Pickering Pick: Diseases of the Ends of the Long Bones in Children.

Saturday, June 23rd.

London Post-Graduate Course.—Bethlem Hospital.—At 11 a.m., Dr. Hyslop: Insanity with Cardiac Disease, Phthisis, Gout, &c.

Monday, June 25th.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Acne and Rosacea.

Vacancies.

alrothery Union.—Medical Officer. Salary £90 per annum, and £10 per annum as Medical Officer of Health. Election 27th June.

Bootle Borough Hospital, Derby Road, Bootle.—House Surgeon. Salary £5 per annum, with board, lodging, washing, &c. Applications and testimonials to the Chairman by 19th June.

Cheltenham General Hospital.—Junior House Surgeon (unmarried). Salary £40 per annum, with board and apartments. Applications and testimonials to the Hon. Sec. and Treasurer by 23rd June.

County Asylum, Whittingham, Preston.—Junior Assistant Medical Officer. Salary commencing at £100 per annum, with apartments, board, and washing. Applications and testimonials to the Superintendent.

Darenth School for Imbeciles, near Dartford, Kent.—First Assistant Medical Officer. Salary £160 per annum, rising £20 annually to £200, with board, furnished apartments, attendance, and washing. Applications and testimonials to the Clerk to the Board by 23rd June.

District Infirmary, Ashton-under-Lyne.—House Surgeon. Salary £90 per annum, with board and lodging. Applications and testimonials to the Hon. Sec. by 19th June.

Dorset County Hospital, Dorchester.—House Surgeon (unmarried). Salary £70 per annum, with board and residence. Applications and testimonials to the Chairman of the Committee by 27th June.

Metropolitan Asylums Board.—Assistant Medical Officer at the Western Fever Hospital, Fulham. Salary £15 per month, with board, lodging, and washing. Applications before the 28th inst. (See advert.)

Newport and Monmouthshire Infirmary, Newport, Mon.—House Surgeon. Salary £100 per annum, with board and residence. Applications and testimonials to the Secretary by 23rd June.

Royal Albert Edward Infirmary, Wigan.—Junior House Surgeon. Salary £80 per annum, with apartments, rations, and washing. Applications and testimonials to the General Superintendent and Secretary by 25th July.

Sunderland Borough Lunatic Asylum.—Medical Superintendent. Salary £350 per annum, with furnished house, washing, &c. Applications and testimonials to the Clerk to the Visiting Committee by 30th June.

Appointments

Glassington, C. W., M.R.C.S., L.D.S.Edin., Dental Surgeon to Westminster Hospital.

Goodworth, R. P., L.R.C.P.Edin., M.R.C.S.Eng., Medical Officer of Health for the Winterton Urban Sanitary District of the Glandford Brigg Union.

Hamilton, W. M., M.D., M.Ch.Irel., D.P.H. R.C.P.S.I., Medical Officer for the Sanitary District of Barton-upon-Irwell.

Harrison, R. C., L.R.C.P.Lond., M.R.C.S.Eng., Honorary Medical Officer to the Ealing Cottage Hospital.

Hembrough, J. W., M.D.Durh., L.S.Sc., M.R.C.S., Medical Officer of Health to the County Council of Northumberland.

Mills, R. J., M.B., C.M.Aberd., M.R.C.S.Eng., Medical Officer to the Norwich School Board.

Miller, J., L.R.C.P.Lond., M.R.C.S., Medical Officer and Public Vaccinator for the Iver Sanitary District of the Eton Union.

Norton, J., M.D.Durh., M.R.C.S., D.P.H., Medical Officer of Health to the Vestry of St. Margaret's and St. John's, Westminster.

Powell, A. F. M., M.B., C.M.Ed., Medical Officer for the No. 1 District of the Parish of Sedgley of the Dudley Union.

Robertson, W. J., M.R.C.S.Eng., L.R.C.P.Lond., House Physician at Charing Cross Hospital.

Smith, J. S. K., L.R.C.P.Lond., M.R.C.S.Eng., Honorary Assistant Surgeon to the Stanley Hospital, Liverpool.

Symons, T. H., M.R.C.S.Eng., L.R.C.P.Lond., House Surgeon at Charing Cross Hospital.

Taylor, A. S., L.R.C.P., L.R.C.S.Edin., Medical Officer of Health to the Northern District of the Tynemouth Union Rural Sanitary Authority.

Thompson, C. S., M.B., C.M.Edin., Medical Officer for the Abbotsham Sanitary District of the Bideford Union.

Webb, W. H., M.D.Durh., L.R.C.P., M.R.C.S., Medical Officer of Health to the Kingsbridge Rural Sanitary Authority.

Births.

Bennetts.—June 15tth, at 26 Garden Street, Brompton, Chatham, the wife of J. J. Bennetts, M.B., of a son.

Bryden.—June 15th, at Milton, near Gravesend, the wife of Richard J. Bryden, M.R.C.S., of a daughter.

Fraser.—June 8th, at the Limes, Leigh, Tunbridge, the wife of Frank Fraser, M.D., of a son.

Kent.—June 13th, at 3 Minard Terrace, Partick Hill, Glasgow, the wife of R. T. Kent, M.A.Oxon., F.R.C.S., of a daughter.

Snow.—June 9th, at 6 Gloucester Place, Portman Square, the wife of Herbert Snow, M.D.Lond., of a son.

Marriages.

Collier—Young.—June 12th, at St. Bartholomew's, Dublin, Horace Stansfield Collier, F.R.C.S., to Margaret Constance, daughter of the late Robert Young, Esq., of Clontarf, Dublin.

Cutcliffe—Hayward.—June 13th, at St. Clement's, Liverpool, Montagu Cutcliffe, L.R.C.P., M.R.C.S., of North Tawton, Devon, youngest son of George Cutcliffe, J.P., C.C., of Witheridge, North Devon, to Marion, elder daughter of the late William Hayward, of St. David's, Southsea.

Devereux—Phillips.—June 14th, at St. Nicholas's Church, Kemerton, William Charles Devereux, M.A., M.B.Cantab., of Tewkesbury, son of the late Daniel Devereux, M.D., to Ethel Mary, second daughter of Thomas Phillips, of Kemerton.

Griffiths—Page.—June 13th, at St. Peter's Bromyard, William Arthur Griffiths, M.R.C.S.Eng., L.R.C.P.Lond., of Wonston, Micheldever, Hants, to Marian Annette, eldest daughter of the late George Henry Page, of Hay.

Sankey—Miéville.—June 12th, at All Souls' Church, South Hampstead, Julius Ivor Sankey, M.R.C.S. and L.R.C.P., of Brenchley, Kent, second son of the late George Sankey, M.R.C.S., L.S.A., of Maidstone, to Violet, youngest daughter of Frederic L. Miéville, of South Hampstead.

Deaths.

Chase.—June 11th, at Reading, Francis Edward Chase, M.D., aged 78.

Jolly.—June 9th, at Bournemouth, Robert Jolly, M.D., F.R.C.S.Ed., of Birmingham, and Groveley, Worcestershire.

North.—June 15th, at 61 Monkgate, York, Samuel W. North, M.R.C.S., L.S.A., Medical Officer of Health for York.

Roberts.—June 6th, at Tientsin, F. C. Roberts, M.B., C.M., youngest son of Alderman J. F. Roberts, Manchester.

Sankey.—June 8th, at Boreatton Park, Baschurch, Salop, Herbert Richard Octavius Sankey, M.B.Lond., M.R.C.S., aged 44.

NOTICE.—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

VOL. CVIII. WEDNESDAY JUNE 27, 1894. No. 26.

Original Communications.

THE PRESENT POSITION OF THE LICHEN QUESTION. (a)

By MALCOLM MORRIS, F.R.C.S. Ed.,

Surgeon to the Skin Department, St. Mary's Hospital.

A NECESSARY preliminary to any profitable discussion must be a clear understanding as to the precise meaning attached by those taking part in it to the terms which they employ. In the present instance the question, "What is lichen?" meets us at the threshold, and must be answered before we can proceed further. The proper connotation of lichen has been a good deal debated by dermatologists in recent years without any definite conclusion having been reached. The discussion at the Congress of Dermatology held in Paris in 1889 revealed the widest diversity of opinion among recognised authorities, nor has the work that has been done since that date, interesting and valuable as much of it undoubtedly is, brought us appreciably nearer to a solution of the problem. Much keen observation and argumentative subtlety have been displayed in classifying the various conditions to which the term "lichen"—qualified by an infinity of limiting and explanatory adjectives—is, or may be, or should (in the the writer's opinion) be applied, and in defining minute shades of difference between one pimply eruption and another, and apportioning to each its exact territory and range of action. These things, however, though interesting and important in their own way, are, after all, only details, and the question, "What is lichen?" which lies at the root of the whole matter, still remains without an answer. Till that question has been settled no real progress is possible; if we can succeed in clearing up this one point the present meeting will not have been fruitless. My own share in the work must be confined to the humble but necessary part of the backwoodsman; I will try to clear the ground leaving the tillage of it to abler hands.

What, then, is lichen? Is it a *disease*, that is to say, a definite pathological state characterised by distinctive lesions variable in degree and type as the manifestations of disease in different persons must necessarily vary, but expressions of the same fundamental process? Or is it a local condition—a lesion, in short—that may be common to several diseases? That is the question to be decided.

In predermatological days lichen seems to have meant nothing more definite than a disorder of the skin in which slightly itching pimples were the most prominent feature. Willan defined it as "an extensive eruption of the papulæ, affecting adults, connected with internal disorder, usually terminating in scurf, recurrent, not contagious." Since his day the meaning of the term has been extended so as to include the most divers conditions which have nothing in common but the fact that at some time or another a papular eruption has been one of the clinical phenomena. As the first Napoleon said of the Italy of his day that it was not a nation but a geographical expression, so might it have been said of lichen not many years ago that it was not a disease but an anatomical expression. Or rather, it was a pathological Hinterland which, while nominally an independent territory, had its autonomy almost obliterated by the "spheres of influence" of other processes such as eczema, syphilis, pityriasis, &c. An unquestionable evidence of progress is afforded by the process of *decortication*, if I may be allowed the expression, whereby the conception of lichen has in recent years been cleared from the mass of extraneous material with which it had become encrusted. Thus the lichen circumscriptus and lichen circinatus of the older writers have been restored to their true nosological place. Among the seborrhœal eczemas, lichen urticatus is claimed by urticaria; lichen pilaris has been identified as pityriasis pilaris. Lichen strophulosis is a form of miliaria, and syphilitic lichen is part and parcel of the great irritative disease of which it is a product. Lichen simplex and lichen agrius are now believed by most dermatologists to be modifications of eczema. By this process of elimination the number of lichens is reduced to one, viz., the disease described by Erasmus Wilson as lichen planus, which I believe to be identical with the lichen ruber of Hebra. At the Paris Congress Kaposi[1] reduced the lichen group to two diseases—1. Lichen ruber, with two subdivisions (*a*) acuminatus, and (*b*) planus; 2. Lichen scrofulosum. Lichen ruber acuminatus, he contended to be by Hebra's own admission the same condition which has been named lichen ruber by the latter, and he showed drawings of it "dating from the time of Hebra," which he said illustrated very well "the small red conical papules, covered with a white top composed of epidermic scales, papules discrete or arranged in lines or rows, or scattered over wider areas, and giving the skin an appearance like *cutis anserina*, and to the touch a sensation like that of a file, patches of redness and widespread infiltration set in a frame of similar papules, scaly or deeply furrowed, thick and hard, the furrowed condition of the soles and palms, and the folds on the flexor aspects of finger joints, the arrangement in groups and circles of the papules on the dorsal surface of the phalanges of the fingers, the degeneration of the nails, the ectropion of the eyelids, the alopian of the hairy scalp, the atrophy of the hairs and eyebrows" associated with subjective symptoms such as itching, shivering, insomnia, &c.[2] Kaposi further stated that he considered lichen ruber acuminatus to be identical with the affection described under the name of pityriasis rubra pilaris by Devergie and Besnier. Nothing could more strikingly show the confusion in which the whole subject was involved than that after Kaposi's exposition of the gospel according to Hebra, Hebra's son (Hans von Hebra) should have risen to call his brother-in-law's exegesis in question, contending that the lichen ruber of Hebra was radically different from pityriasis rubra pilaris by the whole distance separating a grave constitutional condition from a skin affection which left the general health untouched. In this view he was supported by Jamieson,[3] and C. Boeck,[4] and Unna[5] said that if lichen ruber acuminatus were to be held as identical with pityriasis rubra pilaris, it could not be maintained that the former condition was the same

---

(*a*) Paper read before the International Congress at Rome.

as the lichen ruber described by Hebra! Unna, therefore, disowning any connection with the "acuminatur" variety as given over by Kaposi himself to pityriasis rubra pilaris proposed to add the epithet "neuroticus" to complete Hebra's original designation on the ground that not only the skin but the nervous system is involved in the process (as in leprosy) and it is this which in advanced cases leads to the marasmus and other serious constitutional symptoms which are the distinguishing characteristics of the condition described by Hebra. It was pointed out by Schwimmer,[6] however, that "neuroticus" was a question—begging epithet in as much as the neurotic origin of the disease had yet to be proved. He added that Hebra himself had modified his views as to the invariably fatal character of his lichen ruber so that this could not rightly be put forward as an absolutely distinctive featnre. Schwimmer further expressed his agreement with Kaposi as to the identity of lichen ruber acuminatus with pityriasis rubra pilaris. Schiff,[7] while continuing to regard the gravity of the constitutional symptoms as an essential part of the conception of lichen ruber, suggested that cases of the acuminate variety would be found to resolve themselves according as the skin eruption was or was not accompanied by serious constitutional disturbance into lichen ruber (Hebra) and pityriasis rubra pilaris. Besnier, while accepting the identity of lichen ruber acuminatus described by American dermatologists such as Taylor and Robinson, more than hinted a doubt as to the right of Hebra's lichen ruber or Kaposi's lichen ruber acuminatus to a place in the nosology of skin disease. He took Wilson's lichen planus as the basis of his classification of the varieties of lichen which he gave as follows:—(*a*) Lichen with predominance of small papules—the type of the acuminate variety; (*b*) lichen with exclusively flat papules—the pure type of the disease described by Wilson; (*c*) lichen with flat and acuminate papules co-existing—mixed form very common; (*d*) lichen with large "giant" papules, Unna's lichen obtus, Kaposi's coral grain or moniliform lichen; hypertrophic lichen, &c. This is the list as constituted by Besnier, who further reserved the right of adding to their number when any new variety such as Unna's "neuroticus" had fully established its claim to recognition. De Amicis pleaded for the retention of the divison of lichen ruber planus and lichen ruber acuminatus with a further group of lichen corneus; he added that both forms might be present in the same individual. Leloir suggested that in view of the confusion in which the whole subject was involved the lichen group should be abolished till fuller knowledge of its nature, morbid anatomy and pathogenesis has been attained. Hallopean also denounced the grouping of a number of different diseases under the head of lichen; that name he argued should be restricted to the affection described by Wilson as lichen planus. That constituted a morbid entity, but the epithet "planus" applied only to a particular variety of the disease of which there were two forms, acute and chronic. The chronic form included the varieties described under the names of lichen planus, obtusus, acuminatus, tuberosus cornous, coral necklace, and sclerous, while the acute comprised a part of the cases published under the name of lichen ruber acuminatus.

This brief summary of the views expressed at the Paris Congress will suffice to show how far dermatologists were, four years ago, from being unanimous even as to what constitutes lichen. On the whole, however, there was a practical consensus of opinion among the representatives of the French school that there is only one *disease* to which the term "lichen" is justly applicable, and that is the lichen planus of Wilson which constitutes a type of which all other forms are varieties. Kaposi and the Vienna school on the other hand hold on by the lichen ruber of Hebra as the typical lichen, but with a fundamental difference of opinion as to the nature of the disease indicated by that name. Lichen planus Kaposi looks upon as a variety of lichen ruber, that is to say his lichen ruber acuminatus, "the acuminate being transformed into the flat form during the evolution of the infiltration and the scales under the influence of arsenic."[8]

Since the date of the Paris Congress comparatively little has appeared on the subject of lichen, and what has been published relates chiefly to the point in controversy between Kaposi and his critics, viz., the identity or non-identity of lichen ruber acuminatus and pityriasis rubra pilaris.

Hans von Hebra[9] classifies the forms of lichen as follows:—(1) Lichen ruber acuminatus (neuroticus, constitutionalis), first described by Hebra, running an acute course and spreading quickly over the whole body, and dangerous to life. (2) Lichen ruber miliaris (planus universalit, obtusus) called by Unna "universal lichen miliaris." The lesions are flat or blunt papules of the size of a pin's head, some of which spread at the edge and form shapes like pearl strings with a depressed and pigmented area in the centre. The affection may spread rapidly, but it is not attended with immediate danger. Two cases of "lichen planus miliaris" running an acute course have been recorded by Dubreuilh and Sabrazes.[10] These two forms comprise the affections described by the elder Hebra as "lichen ruber." (3) Lichen ruber planus localis (verrucosus, cornutus), the lichen planus of Wilson, very chronic, seldom affecting large areas; the patches are generally not larger than the palm of the hand, and gradually become covered with a warty, horny, firmly adherent layer of epidermis. That lichen ruber acuminatus and lichen planus are intimately related is shown by that they may coexist or alternate with each other. Neumann[11] contends that while lichen planus and lichen ruber acuminatus are closely allied, pityriasis rubra is an independent disease altogether distinct from the latter. The results of microscopic examination show that while in lichen, whether of the "planus" or "acuminate" variety, the seat of the disease is mainly the corium, in pityriasis rubra pilaris the changes are almost entirely confined to the epidermis. At the Third Congress of the German Dermatological Society held at Leipzig in 1891,[12] Galewsky maintained (1) that pityriasis rubra pilaris (Devergi-Besnier) is identical with the affection described under the name of lichen ruber by the American writers, Taylor and Robinson, and with a large number of cases described as mild forms of lichen ruber acuminatus (Kaposi); (2) that pityriasis rubra pilaris is an exfoliative hyperkeratosis, quite distinct from the lichen planus of Wilson; and (3) that lichen ruber acuminatus (Hebra-Kaposi) must still be regarded as a disease *sui generis*. In the discussion which followed Neisser expressed the opinion that pityriasis rubra pilaris (which he prefers to call Keratosis rubra pilaris) is not the same as lichen ruber acuminatus, the former being a comparatively trivial, the latter a very grave, affection. Kaposi reiterated his belief that the conditions are, in spite of minor differences, substantially identical, but he admitted that he had not made up his mind whether the process is a Keratosis or a lichen. Neumann took this as indicating that the difference between pure Keratosis and lichen was the absence of inflammation in the former and its presence in the latter process. The whole subject has recently been exhaustively reviewed by E. von Düring, of Constantinople.[13] He protests against the confusion which has been introduced into the subject by Kaposi's identification of lichen ruber acuminatus with pityriasis rubra pilaris, pointing out that if this contention be admitted it follows that Hebra's lichen ruber—said by Kaposi to be the same as his lichen ruber acuminatus—is identical with pityriasis rubra pilaris. Further, inasmuch as Hebra and Wilson agreed that their respective "ruber" and "planus" varieties of lichen were substantially the same disease it follows, on the geometrical principle that two things which are equal to a third are equal to each other, that pityriasis rubra pilaris is also identical with lichen planus—which is absurd, as Euclid says.

Düring defines lichen as a dermatosis which, when fully developed, is characterised by isolated or agglomerated papules, situated on the cutis, the process only secondarily involving the epidermis. The papules itch more or less, and when the affection has lasted a long time the skin becomes thickened and pigmented, and its natural folds are more or less exaggerated. The word "ruber" should be omitted from the name of the disease, as the epithet is inapplicable in many cases. "Planus" and "obtusus" are adjectives describing certain appearances in local or universal lichen. Düring proposes the following scheme of classification:—

Lichen.

A. Lichen Localis (almost always chronic).
  (a) *Lichen planus*—
    1. Lichen planus simplex (Wilson).
    2. " " annularis (Unna).
    3. " " corneus, verrucosus, hypertrophicus (Vidal).
    4. " " scleroticus, atrophicus (Hallopeau).
  (b) *Lichen obtusus* (Unna).
  (c) Lichen miliaris.
B. Lichen Universalis.
  (a) *Lichen planus*—
    1. Lichen planus simplex (Wilson).
    2. " " annularis.
  (b) Lichen multiformis.
  (c) Lichen obtusus.
  (d) Lichen moniliformis.
C. Lichen Neuroticus.

Brocq and Jacquet[14] say that a basis for the constitution of the lichen group is to be found in the presence of an initial lesion of papular character. According to them the lichen simplex of Vidal, which, as already said, is now generally regarded as eczema constitutes a distinct type of skin affection to which they apply the name of *Névrodermites*. They define this as a class of affections in which the primary symptom is exclusively nervous. First there appear spots of hyperæsthesia, and on these the inflammatory lesions develop in response to irritation and scratching. The disease is, therefore, essentially pruriginous, the eruption, that is the papules, the circumscribed patches and the pigmentation are the results of scratching. Vidal[15] himself also pleads for the readmission of chronic lichen simplex to the lichen group by the side of lichen planus and other forms. Then he is willing that the whole group should be absorbed into the class of *Névrodermites*. At the International Congress of Dermatology held at Vienna in 1892 Brocq[16] presented his full scheme of classification of pruriginous diseases which he arranges in three groups: (1) Neurodermiæ comprising pruritus and all conditions in which there is itching without visible lesion (that is, without reaction to scratching); (2) Neurodermitis pura with primary "lichenification." This class is subdivided into (a) Neurodermitis diffusa—Lichenificatio abortiva diffusa primaria; and (b) Neurodermitis circumscripta chronica—Lichenificatio primaria pura circumscripta chronica (Lichen simplex chronicus of Vidal); (3) Neurodermitis eczematosa lichenificatia; (4) Neurodermitis chronica polymorpha (type prurigo of Hebra); (5) Neurosis cutanea urticaria (type Lichen simplex acutus of Vidal); (6) Neurosis cutanea urticaria pura; (7) Neurosis Cutanea (type Dermatitis herpetiformis); (8) Lichen ruber. The element common to the numerous diseases included under these heads is the existence of a peculiar neurotic condition of the skin. *Lichenification* is, as I understand it, the response of the neurotic and irritable skin to mechanical irritation (as by scratching) in the form of papules.

From this survey of the literature of lichen which has appeared since the Paris Congress, it appears that we are as far as ever from an understanding as to the precise connotation of the term lichen. Where dermatologists of such eminence as many of those that have been named differ so widely I cannot hope to reduce the discord to harmony. *Non nostrum tantas componere lites.* My own view is still as I expressed it at the Paris Congress[17] that much of the discussion on the subject has turned on mere names. It seems to me that a pimply eruption is just as adequate a basis for a classification as scaliness or extravasations of blood; in other words, lichen has no more right to be erected into a group than pityriasis or purpura. After sorting out of the lichen group those elements that belong to definite diseases such as eczema, syphilis, &c., the only affection left is lichen planus. Having had the opportunity of studying some of Wilson's cases, and those of Hebra, under that great dermatologist's own guidance I was able to satisfy myself that they are substantially one and the same disease. Lichen ruber acuminatus on the other hand seems to me to be identical with pityriasis rubra pilaris, and if I had felt any doubt on the subject before, the unhesitating way in which a case of lichen ruber acuminatus shown by Schwimmer at Buda Pesth after the Vienna Congress last year was at once identified as pityriasis rubra pilaris by the French dermatologists present would have removed it.

The lichen group is thus reduced to a single disease. Lichen planus as described by Wilson may be taken as the typical form of which various modifications occur according to the extent and severity of the process, the implication or otherwise of the general health, the predominance of one or the other of the natural characters of the eruption, and accidental alterations in the appearance of the lesions. I entirely concur with Brocq in the view that in classifying diseases regard should be had not only to the external appearances but to their pathogenesis and mode of evolution. The tendency of modern pathology is to name diseases in accordance with the processes which are believed to underlie their manifestations, and—when these are known—the causes which set the processes in motion. In dermatology, as in other departments of medicine, the beginning of wisdom is to recognise the limitations of our knowledge. If we look the question propounded for discussion straight in the face, the reason of all the difficulty surrounding it becomes plainly visible. The plain truth is that at present we are too ignorant of the pathological conditions which express themselves on the skin in the form of lesions to which we give the name of lichen to be in a position to enumerate, much less to classify, them. It would be better, therefore, to eliminate the word "lichen" from our terminology as being often misleading, and at best meaningless.

So long, however, as papular eruptions, manifestations of definite diseases (syphilis, eczema, &c.) are excluded from our conception of lichen, and that term is employed in a well-defied sense, as a convenient symbol for certain clinical phenomena, there can be no objection to its use. It should be understood as indicating an eruption, of which the elementary unit is a papule which does not spread at the edge, and does not develope into a vesicle or a pustule.

It appears to me probable that the process which results in the production of the lesions which we designate by the term lichen planus is initiated by a variety of factors. So far as I am aware a microbic origin has not been suggested, but at the present day it would be rash to deny the possibility of such a pathogenesis. The serious disorder of the general health as compared with the absence of such a complication in others seems to indicate a fundamental difference either in origin or in evolution of lesions apparently similar. That lichen is sometimes of nervous origin I am firmly convinced; I have seen some striking instances in which the disease has immediately followed a severe mental shock, and others in which it was associated with very marked neurotic symptoms. The association of neurotic conditions with lichen has been strongly insisted on by Unna, and Köbne and confirmatory evidence has been supplied by Dubois-Havenith, and others. I am not prepared, however, to follow Brocq in his sweeping proposal that lichen should be swallowed up in "neurodermitis."

In conclusion, I venture to plead for fuller clinical and pathological investigation before further theories are formed or schemes of classification elaborated. It is not classification that is wanted at present so much as facts. Let cases be observed carefully with the single-minded endeavour to *see things as they are*, and not as they should be to fit in with or contradict some theory. Above all let them be studied all round, that is to say, not only in their manifestation on the skin, but in all their relations. At present our business, it seems to me, is to *learn* what lichen is by the comparative study of actual cases, not to *reason* about it on the basis of verbal descriptions.

I may sum up the gist of these remarks in the following propositions:—

1. Lichen is not a disease, but a type of lesion.
2. The term should be reserved for the clinical entity described by Erasmus Wilson under the name of lichen planus which is the same as Hebra's lichen ruber.
3. The affection described by Kaposi under the name of lichen ruber acuminatus is identical with that described by Devergie and Besnier as pityriasis rubra pilaris.
4. Other forms of lichen—obtusus, hypertrophicus, verrucosus, &c.—are variants of the typical form, the Hebra-Wilson lichen ruber planus.
5. The group of symptoms to which the name of lichen planus is applied is probably caused by a variety of factors, but at present we are almost entirely in the dark as to its pathogenesis.

Mr. N. C. Macnamara, Vice-President of the Royal College of Surgeons, England, and Mr. John Tweedy have been elected the representatives of the College to serve on the Civil Rights Defence Committee, formed to raise a fund to enable Mr. R. B. Anderson, F.R.C.S.Eng., to bring to decision, by appeal to the Judicial Committee of the Privy Council, judgments and orders of the Court involving civil rights of high and general interest to the profession.

An election of Professors and Lecturers will be held by the Council of the Royal College of Surgeons of England next month. Candidates must send in their applications by to-morrow, the 28th inst.

THE ETIOLOGY, PREVENTION, AND TREATMENT OF PUERPERAL SEPTICÆMIA. (a)

By THOMAS MORE MADDEN, M.D., F.R.C.S.Ed.,

Obstetric Physician and Gynæcologist, Mater Misericordiæ Hospital; Consulting Physician to the Children's Hospital, Dublin; Consultant and Ex-Master, National Lying-in Hospital; Hon. President, First International Congress of Obstetrics and Gynæcology, &c.

Although recent bacteriological investigations have apparently brought us within a measureable distance of accurate knowledge of the general causation and prophylaxis of puerperal fever, or septicæmia, as will probably result in a corresponding advance in its treatment; nevertheless, on all these points there still remains abundant need for all the light that can be thrown on the subject by clinical experience as well as by scientific research. From the former standpoint the writer may therefore submit the following observations, founded on a long and familiar acquaintance with puerperal fever in hospital and consultation practice in the hope of also eliciting the opinions of other members of the Academy of Medicine on several questions of no little importance.

Etiology.—Under the heading puerperal fever, or septicæmia, are here included all forms of infectious pyrexial disease directly consequent on parturition, whether peculiar to the puerperal condition or then assuming a specific character. These, however, modified in their prevailing type and predominant symptoms by the special circumstances of the patient, or by the source and intensity of the septicæmic poisoning in each instance, are all primarily ascribable to the invasion and development of pathogenic micro-organisms, in some cases identical with the streptococci of erysipelas or other infective diseases. In one or other of these pathological microbes must be recognised the starting-point of what was formerly termed autogenetic puerperal fever—*i.e.*, that connected with putrefactive changes in retained placental or membranous *débris*, clots, or discharges to which such germs have gained access, as well as of those very frequent cases in which parturient lacerations of the cervix uteri, vagina, or perinæum furnish the channels for septic infection. Moreover, in bacteriological causes we find the most rational explanation, both of the occasional epidemic diffusion and of the local prevalence of septicæmia, to the air-borne germs, of which lying-in women have so often and so fatally proved their special susceptibility. These germs may thus be conveyed by other channels than those just referred to into the system of the puerperal patient; as, for instance, from exposure to sewerage gas or foul air in unsanitary dwellings, or from an atmosphere specifically contaminated by puerperal exhalations, as in lying-in hospitals. The wards of the latter, therefore, should never be occupied in unbroken succession, nor without a sufficient interval and thorough disinfection between each new batch of obstetric cases, nor, moreover, without provision for fully 2,500 cubic feet of space for each patient.

The prophylaxis of puerperal septicæmia largely depends on the sanitation and maintenance of the constitutional condition of our obstetric clients, by judicious hygienic and dietetic measures, before delivery, supplemented, when not specially contra-indicated, by ferruginous tonics throughout the latter months of pregnancy. Secondly, the vital importance of asepsis in everything relating to the patient, her surroundings and her attendants during delivery, and the puerperium cannot be too strongly insisted on. At an early period during labour, and again before its termination if protracted, as well as after delivery, the vagina should be washed out by warm antiseptic irrigation, with either carbolic (1 in 40), boric acid (1 in 25), or lysol (1 in 100) solution. The (1 in 1,000) bichloride of mercury solution recommended by some authorities, although a potent germicide, is an unsafe uterine application after delivery, and is here mentioned only to be condemned for that purpose. But for the cleansing of the external genitalia during or after labour, a (1 in 2,000) solution of this salt may be employed by means of wood-wool pads, which should be destroyed immediately after use. I regard the routine practice apparently relied on by some obstetricians—of merely dipping the hands in an antiseptic solution before touching the lying-in women—as only valuable as an adjunct to absolute cleanliness, and without the latter, as too often employed, being utterly delusive as a safeguard against sepsis, and therefore far worse than useless. Such obstetric manual cleanliness as is essential before any vaginal examination or contact with the lying-in or puerperal patient can only be secured by diligent hand-scrubbing with clean hot water and soap, by means of the nail-brush, after which, and not before, the hand may and should be immersed in the antiseptic solution prior to touching the patient.

(a) Abstract of paper read before the Obstetric Section, Royal Academy of Medicine, Ireland, May 18th, 1894.

Thirdly, on the completion of labour, and, above all, more especially whenever that has been tedious, instrumental, difficult, or complicated, the uterine cavity as well as the vagina should be thoroughly flushed out with hot boric or carbolic solution, or peroxide of hydrogen. For this purpose the irrigator should invariably be employed, as the ordinary syphon syringe, when misused for uterine injection shortly after delivery, is extremely liable, as exemplified by cases referred to by the writer, to force the injected fluid, or even air, through the Fallopian tubes, giving rise to metro-peritonitis, or into the then patulous uterine sinuses, and may thus possibly occasion death from embolism.

Treatment.—Although the prevention rather than the treatment of puerperal septicæmia is the object to which the obstetrician may most profitably direct his attention, the latter subject cannot be here omitted from consideration, and must be chiefly guided by the special type of the disease, as well as by the predominant symptoms and condition of the patient in each instance. In the now more prevalent typhoidal form of puerperal fever, the disease is distinctly of a remittent character, as shown in several clinical charts exhibited. For its treatment free stimulation, suitable nutrition, and strict asepsis by local irrigation of the urethro-genital tract are essential; whilst in the way of medicine there are only three drugs which appear to the writer as possessing any approach to specific, remedial, or germicidal action in such cases—viz., quinine, sulphurous acid, and turpentine.

Turpentine.—In all cases of puerperal fever in which the use of rectified spirits of turpentine may be tolerated by the stomach and bowels, the writer believes that no other remedy is of such general utility as this, the efficacy of which (like so many other obstetric ideas the credit of which has been given to modern foreign authorities) was originally demonstrated in this city by a long-forgotten Irish practitioner, Dr. Brennan, upwards of eighty years ago. The remedial action of turpentine in appropriate cases of puerperal fever, I have had proved by my own experience, and ascribes to the probable germicidical patency of the drug no less than to the effect of a powerful stimulant. Besides, there are other agents available in accordance with the special symptoms and stage of the disease and condition of the patient in each case, which need not be referred to, as their employment must obviously be directed by the broad principles of general therapeutics. In the earlier stage of puerperal fever no remedy has afforded such advantage in reducing temperature and pulse-rate, unlocking pent-up lochial and mammary secretions, inducing sleep and tranquillising the patient, as phenazone in small and repeated doses. The effects thus produced are, however, too frequently but temporary, and in the latter stages of puerperal septicæmia, or where from the first the intensity of the puerperal septicæmic intoxication and consequent prostration are most marked, then, it is almost needless to add, antipyrin is distinctly contra-indicated.

◆

NOTE ON

THE FORMATION OF UREA IN THE LIVER AFTER DEATH.

By M. CHAS. RICHET,

Professor of Physiology in the Faculté de Médecine.

[FROM OUR OWN CORRESPONDENT.]

At the last meeting of the Académie des Sciences, Prof. Richet brought forward a communication on the above subject, of which the following *résumé* will doubtless be read with interest.

He said it is one of the fundamental principles of general physiology that the tissues continue for a certain time after circulation and sanguification have ceased, to exercise the same functions as during life. That is to say, that the death of the individual does not involve the immediate and simultaneous death of the anatomical parts of which he is composed.

A remarkable example of this chemical action following the death of the individual is the production of sugar in the liver. Claude Bernard in a memorable experiment proved that the formation of sugar at the expense of hepatic glycogen continues during several hours in a liver removed from the body, and washed immediately after death by a current of water which carries away all the blood contained in the vessels. M. Richet has studied in the same way the production of urea in the liver. The greater number of physiologists admit, in fact, that the liver is one of the principal organs in which urea is produced, and pathology confirms this opinion by numerous proofs.

If, then, it is true that the liver forms urea during life, it ought to continue to form it for some hours after death while the vitality of the hepatic cells has not been destroyed, and M. Richet has performed a number of experiments which establish this fact.

There is formed in the liver withdrawn from the body and deprived of blood, a relatively considerable quantity of urea, since in four hours, it amounts to more than ·7 gram per kilogram. This gives in twenty-four hours more than 4 grams of urea.

The significance of these experiments has been singularly exposed by the researches of MM. Gautier and Landi, who have shown that muscle continues after separation from the body to live and form leucomains and alkaloids at the expense of the nitrogenous matters which it contains. In the same way, M. Richet's experiments prove that the liver left to itself and removed from the body continues to produce urea. There thus exists a remarkable analogy between the formation of sugar and the formation of urea in the liver. The two phenomena are produced by aid of a soluble diastase.

There occurs besides in a hepatic liquid (fresh liver pounded up and filtered) other interesting phenomena such as production of red colouring matter and *substances reductibles*, but M. Richet only wishes at present to establish one of the most important phenomena of the life of the liver, namely, that the formation of urea is a phenomenon analogous to the phenomena of diastasis.

Selected Prescriptions and Therapeutic Notes.

158.—A Useful Lubricant for Urethral Instruments :—

℞ Glycerini, ʒvij ;
Hydrarg. perchlor., gr. ¼ ;
Saponis mollis, ℥ij ;
Aq. destil, ʒvj.

M. This preparation is antiseptic, and causes no irritation to the urethral canal.—Guyon.

159.—For Pruritus Ani :—

A plug of cotton wool which has been previously soaked in a two per cent. solution of hypochlorite of lime to be introduced into the anus. The plug is left *in situ* until slight smarting is caused. Then it is withdrawn and the anal region is washed with the same solution, and afterwards carefully dried.—*La Semaine Medicale.*

160.—For Amenorrhœa :—

℞ Hydrarg. perchloridi, gr. ¾ ;
Sodii arseniatis, gr. j ;
Ferri sulphatis exsiccatæ, gr. xxx ;
Potassi carbonatis, gr. xv ;
Extract : nucis vom., gr. v.

M. (Divide into thirty pills.) One pill to be taken before each meal.—*The Practitioner.*

161.—For Phthisis :—

℞ Creasoti, ♏ vij ;
Iodoformi, gr. vj ;
Acidi carbolici (cryst), gr. viij ;
Ol. theobromæ, q.s.

M. (Divide into thirty pills.) One pill every three hours.

162.—For Whooping Cough :—

℞ Pot. bromidi, gr. xxx ;
Chlor. hydratis, gr. xv ;
Syr. cocainæ, ʒiiij ;
Syr. codeiæ, ʒiij ;
Infus. aurantii, ad. ℥iv.

M. One tablespoonful every three hours.—Señor Don Santiago Ocana.

◆

Transactions of Societies.

THE OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN.

Meeting held Thursday, June 14th.

Dr. Argyll Robertson, President, in the chair.

TWO CASES OF CONGENITALLY DISLOCATED LENSES.

Mr. J. Grosvenor MacKinlay referred to two cases of children of the same family both of whom exhibited symmetrical dislocation of both lenses upwards and inwards. The older of the two was a lad of 19, and was the oldest of a family of nine children, all living and in good health. The other patient was a girl, æt. 15, who was the fourth child. The tension of all the eyes was normal, but both children presented well-marked myopic crescents. He mentioned incidentally that the mother related having been subjected to frights previously to the birth in each instance, and in respect of the girl labour was precipitated by a fright at seven months.

OPTIC NEURITIS IN RELATION TO CEREBRAL TUMOUR AND TREPHINING.

Dr. James Taylor read a paper bearing on the subsidence of optic neuritis after operation undertaken with a view to the removal of cerebral tumours even when such tumour was not removed. Observations had been recorded by Brum and Erb, and he emphasised the fact that this took place not only in cases in which the tumour was removed from the brain, but also in cases in which, though the skull was opened, the tumour was not removed or interfered with. He related three cases of optic neuritis associated with intra-cranial tumour in which the tumour was removed and in which the operation was followed by subsidence of the optic neuritis. A second group of three cases were patients who exhibited symptoms of intra-cranial tumour. All were trephined, and in all of them, although the tumour was visible at the operation, it was not removed or even incised. Yet the neuritis in one absolutely disappeared, although when the patient subsequently died, a tumour was found to be present. In the second case the swelling had diminished by one millimetre, although the tumour obviously continued to grow and the patient has since died after passing from under observation. In the third case the symptoms pointed to a cerebellar growth, probably tubercular, but no tumour could be found at the operation, yet the swelling of the discs which was present disappeared, although slight impairment of vision remained in one eye. The third group of cases, also consisting of three, comprised one patient from whom a cerebral tumour was removed, and the neuritis which was present in only one eye disappeared. He subsequently died, and a cyst was found occupying the seat of the tumour which had been removed. There was no recurrence of the neuritis when he was last seen, three weeks before his death. The second case of this group was that of a boy who was trephined on account of right-sided fits. Optic neuritis was present. A cyst was tapped and a drainage tube kept in intermittently during two years. The tumour went on growing, and the boy died, when sarcomatous masses were found *post mortem* throughout the brain. The neuritis subsided after the first trephining and drainage, and never recurred during the subsequent two years. The last case was that of a man at present in hospital from whose brain a sarcomatous growth was removed. His optic neuritis disappeared, and had never recurred, although at a subsequent operation, undertaken on account of symptoms of recurrence, it was found impossible to remove it. He urged in conclusion that there was evidence that a large cerebral tumour might be present without producing optic neuritis, and that optic neuritis might be present without cerebral tumour, a fact which had long before been pointed out by Hughlings Jackson and Gowers. These observations make it evident that, in certain cases of intra-cranial tumour, the pressure inside the skull was the effective agent in producing what is known as optic neuritis.

Dr. Hughlings Jackson said the cases tended to prove that in some instances, at any rate, intra-cranial pressure was an important factor in the production of optic neuritis. The size of the tumour was apparently not a predominant factor in determining the production of optic neuritis, and large tumours might certainly exist without this phenomenon being present. He referred to a case of his own in which this was so, and to another in which there was optic neuritis and no tumour, also to a case of the same kind published by Dr. Percy Smith in which the symptoms pointed to general paralysis though it proved to be cerebral tumour. Dr. Savage, on the other hand, had reported a case in which symptoms of intra-cranial tumour proved to be due to general paralysis of the insane. He alluded to three cases of unilateral optic neuritis in which the cerebral tumour was on the opposite side to the lesion, cases, he observed, which were difficult to explain on any hypothesis. He referred to the valuable assistance in unravelling these questions which had been afforded by the experimental researches of Messrs. Horsley and Spencer on the effects of artificially raised intra-cranial pressure. In reference to the fact that patients with optic neuritis sometimes died suddenly with symptoms of respiratory failure he pointed out the analogy between this failure on the part of the respiratory centre and the sudden functional impotence which was often observed in respect of the optic nerve in these cases. He suggested that the respiratory failure might be due, as suggested by Buzzard, to an affection of the vagus similar to that observed in the optic nerve.

Mr. Victor Horsley said the facts pointed to the pathological connection of cerebral tumour with optic neuritis being one due to several complex factors, one of which was doubtless intra-cranial pressure. He admitted that trephining, by removing the intra-cranial pressure, led to subsidence of the neuritis but this, he added, did not explain what were the several factors involved, nor did it explain the association of optic neuritis with cerebral tumour. He insisted on the fact that no reduction of pressure could have a beneficial effect when much optic atrophy was present, and even if treatment by trephining were approved of in cases of optic neuritis in the hope of checking its further progress, this was not justifiable if much atrophy were present. He further pointed out that the subsidence of the neuritis after removal of part of a growth was not followed by recurrence, even though the tumour continued to grow, a fact which he thought disposed of the conclusions formulated by Dr. Edmunds on the pathology of optic neuritis in this association. He asked what results had been obtained with De Wecker's operation. He had heard that they were not what had been and if this were so, he should hesitate to recommend it as an alternative measure in cases of optic neuritis in which for any reason trephining was not thought advisable.

Mr. **Ballance** dissented from the view put forward by the author that intra-cranial pressure was the essential factor in the production of optic neuritis, and he urged that it was not fair to throw aside the results arrived at by Edmunds and Lawford on the strength of the author's cases, seeing that no microscopical examination had been made of the meninges, though these observers had shown that without such an examination it was impossible to know whether or not slight basal meningitis was present.

Dr. **Beevor** said he had seen one of the patients referred to by the author, and although it was now eleven months since the operation there had been no return of the neuritis.

Dr. **Hill Griffith** urged that the pressure theory was the most reasonable hypothesis to explain the production of optic neuritis and it alone explained the sudden recovery of sight of certain patients without operation.

Dr. **Taylor**, in reply, said his remarks were limited to optic neuritis associated with cerebral tumour. Though he was unable to affirm on the strength of microscopical examination that there was not slight basal meningitis in his cases, he was not disposed to think that this was a factor in the production of the optic neuritis.

SOME POINTS IN THE HISTOLOGY OF TRACHOMA.

Mr. R. C. **Ridley** pointed out the great difficulty which was necessarily experienced in carrying out researches such as these, not only in obtaining specimens of trachoma, but also in obtaining specimens of healthy conjunctiva for comparison. The latter difficulty had been overcome by making sections of portions of healthy conjunctiva removed immediately after death from individuals who had died by some independent malady. The sections showed the epithelium of the globe and lids to be stratified, that of the fornices consisting of two or three rows of columnar cells, as well as goblet cells, together with a variable amount of lymphoid tissue in the sub-conjunctival layer. This lymphoid tissue was found under all mucous membranes, and was called "sentinel" tissue by physiologists. It had the function of preventing deleterious organisms or poisonous chemical products from gaining access to the blood, *e.g.*, particles of coal, steel, or stone in the lungs, and peptones from the intestine were thereby re-converted into proteids. Hypertrophy of this lymphoid tissue occurred where increased work was thrown upon it. An increased amount of lymphoid tissue was not *per se* a disease, but evidence of the reaction of the organism to the attacks of some outside injurious body or agent. In trachoma rapid proliferation of the cells formed rounded elevations, covered only by a delicate epithelial layer, whose approximation formed grooves, and sometimes cavities. Some authors had described a fibrous investment to the follicles, but none such was present, as a rule, in the specimens which they had examined. The follicles were principally formed by proliferation of original lymphoid tissue, the infiltration consisting of wandering leucocytes. The follicles belonged to the class of infective granulomata, differing from the ordinary forms of granulomata in containing healthy blood-vessels, and no giant cells. He referred to the great diversity of opinion which obtained as the etiology of trachoma. In the obstinate cases there was most probably a specific cause. Many kinds of micro-organisms had been described, but inoculations had not given satisfactory results. Moreover, in normal conjunctiva many kinds of bacteria were found, so that it was difficult to obtain trustworthy evidence about any particular variety. The changes in trachoma began in the fornices (1) by proliferation of the cells ; (2) by deepening of the folds, forming in some cases cysts ; (3) an increase in the goblet cells ; (4) by the appearance of ovoid bodies. Later on the epithelium is shed except in the crypts. That in the crypts and at the periphery reproduced the new epithelium. He alluded to Muttermilch's view that this epithelium was healthy, this point being made the basis of his argument against the existence of micro-organisms in trachoma. In reality this enclosed epithelium appeared to be the most affected. The globular bodies described by Reid and Muttermilch as "goblet" cells were probably not so for the following reasons :—(1) They were too numerous ; (2) they were found where goblet cells are not ordinarily present ; (3) many of them were not in contact with the surface ; (4) their long axis was not always perpendicular to the surface ; (5) they stained differently. These globular bodies strongly resembled the oval bodies of molluscum contagiosum, which are supposed to be parasitic protozoa. L. Pfeiffer had also observed these bodies, but had not given any opinion about them. Whether in reality they were organisms of that kind he could not say. There were several points against the bacterial origin of trachoma (1) the divergent opinions held by competent observers ; (2) bacterial diseases were usually more inoculable. Those due to protozoa varied widely, *e.g.*, molluscum contagiosum and small-pox ; (3) its power of resisting ordinary germicides ; (4) the absence of giant cells.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, May 18th.

The President, Dr. **Andrew Horne**, in the Chair.

EXHIBITS.

An Anencephaloid Fœtus.—Dr. W. J. **Thompson**, who exhibited this case, read the following notes he made of her case :—Mother, æt. 43 ; married ten years ; had given birth to three children ; two living, both strong and healthy ; last child born three years ago ; had large spina bifida, and died after two days. The exhibit was a typical specimen of anencephaloid monstrosity : the face perfectly developed—mouth, tongue, and eyes, the nose broad and flattened like that of the negro race. The vertical portion of the frontal bone, the two parietal bones, the squamous portion of the temporal, and all the occipital bone (except the base) are wanting. The cervical vertebræ are normal ; there is no spina bifida or talipes, usual in such cases. The following dissection, first, of the anterior portion of the body, shows a right rectus sternalis muscle well developed. This muscle is seldom found in the dissecting-room, but in malformations it is quite common, five out of every six such cases having it. It was not until the researches of Bichat in creating the science of histology, and so reducing the complex structures of the body to their elementary tissues, that the present theory of anomalies and monstrosities was founded—viz., "that of arrest and retardation of development or of excessive formative energy."

A Myomatous Uterus.—Dr. W. J. **Smyly** showed a myomatous uterus which he had removed from a primipara, æt. 40, in the Rotunda Hospital. Upon abdominal examination the uterus was found infested with myomatous nodules, the fœtus presenting in the second position, with the head freely movable above the pelvic brim. *Per vaginam*, a tumour as large as a fœtal head was found occupying Douglas's pouch, and encroaching upon the conjugate diameter to such an extent as to render the passage of the child impossible. The tumour was firmly fixed, and the presenting part could not be reached by the examining finger. Abdominal section was performed on Friday, May 4th, and the uterus drawn out and opened. The fœtus extracted began to cry almost immediately, and is still alive and well. The removal of the tumour was difficult, owing to firm adhesions and to its extensive extra-peritoneal development necessitating careful enucleation. An elastic ligature was placed around the cervix, below the tumour, and the latter, with the uterus, removed. The stump, too short to be treated extraperitoneally, was extirpated *per vaginam*, the broad ligament having been secured by clamps. A large mass of tissue was, however, found outside the clamp on the left side, and another clamp having been placed outside of this, is was removed, and upon examination was found to be a second uterus, with a normal non-pregnant cervix, which easily admitted a uterine sound. The patient developed a thrombosis in the short saphenous vein of her left leg, but was progressing favourably.

Dr. **Alfred Smith** stated that the patient originally came to him complaining of great pain and cessation of menstruation. The signs of pregnancy were so badly marked that it was only when abdominal section had been performed with a view to removing the uterus, and the uterus grasped and *ballottement* obtained, that the diagnosis of pregnancy was established. The wound in the abdominal wall was immediately stitched up, and the case allowed to go on to full term. Some severe pain a few hours after seemed to threaten a miscarriage, but the pain was allayed by morphia, and the patient got quite well.

Dr. **Purefoy** related the history of a somewhat similar case which had come under his care. A lady came to him last autumn, complaining of a hard lump in her abdomen and of cessation of menstruation for the past six weeks. She was forty years of age, and had been married ten years. He examined the woman and concluded that she had a large fibroid of the uterus, and he told her not to be alarmed at the cessation of menstruation, as that was rather a favourable thing, and that she should go home and not be anxious about herself. Dr. Smyly also saw the case, and considered it to be one in which operation should be refrained from. Some three weeks ago he heard from the husband, on writing to inquire after her, that she and her baby were doing quite well. He had no suspicion at the time he examined her that she was pregnant.

Dr. **Smyly** also showed a uterus and double pyosalpinx removed *per vaginam*. The patient was in a very debilitated condition from prolonged hectic fever, which necessitated the operation. He adopted this particular method in consequence of the brilliant results obtained by M. Segond and others, and having had the advantage of seeing the operation performed by Dr. Landau, in Berlin, he was favourably impressed by the result. The operation was not more difficult than an abdominal one would have been, but the left ureter was unfortunately drawn down and included in the clamp. The patient died of peritonitis on the fifth day.

Dr. **Thomas More Madden** read a paper on "The Etiology, Prevention, and Treatment of Puerperal Septicæmia," which will be found in another column. In the discussion that followed

Dr. **E. Hastings Tweedy** said that he was glad to hear Dr. Madden gave preference to aseptic instead of antiseptic treatment. Students were apt to imagine that merely dipping their hands in a solution of corrosive sublimate rendered the conduction of labour, as far as infecting the woman was concerned, devoid of danger. They did not realise, as a rule, that they must have their instruments laid on aseptic material, and that the basins they used must be rendered aseptic. He also said that the experience of large maternities was against the view that septicæmic infection was conveyed by the air.

Dr. **A. Smith** pointed out the great difficulty met with in private practice, especially in England, in getting a nurse who understood and practised the aseptic or antiseptic management of a case and of obtaining aseptic surroundings.

Dr. **Doyle** drew attention to the necessity of men engaged in midwifery practice refraining from attending infectious cases at the same time.

Dr. **Smyly** emphasised the advantage of aseptic treatment over the antiseptic treatment. He said that Professor Leopold was one of the first to insist on the danger of vaginal examinations, even when made with antiseptic precautions, and of the antiseptic vaginal douche as a prophylactic measure. He thought that prophylactic douchings should be avoided. He had read in the *Lancet*, some three weeks ago, a leading article stating that all that was at present known of value in the management of childbirth, as regards the avoidance of septicæmia, could be found in any book of ten years ago. He did not agree with this, but considered the adoption of the aseptic in preference to the antiseptic treatment to be one of the greatest advancements in obstetrics.

Dr. **More Madden** briefly replied.

The Section then adjourned.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, June 23rd.

On Anæsthetics.

At the meeting of the Académie de Médecine last week, M. Duplay read a report on a case of death by bromide of ethyl in the course of an operation. Hitherto it had been thought that this agent was innocuous, but some recent accidents (two deaths) should render surgeons more circumspect and more prudent in its mode of administration and engage them to take some of the precautions regarded as indispensable when chloroform is the anæsthetic.

M. Laborde drew the attention of his colleagues to a new anæsthetic mixture consisting of nine parts of chloroform and one part of ether. It would seem that this combination acts more promptly and with less danger than when either of these agents are employed separately. Further, the active properties of chloroform are attenuated.

The Heart in Typhoid Fever.

M. Galliard referring to two fatal cases of myocarditis witnessed in the course of typhoid fever, and in which the first bruit of the heart had disappeared several days before death, said that he had treated recently a similar case, but which recovered after a prolonged convalescence. It was that of a young girl, æt. 17, suffering from typhoid fever, and during the illness the first bruit could no longer be heard at the base. The face and extremities were cyanosed, but symptoms of cardiac collapse and syncope were absent. The patient was treated by cold baths.

M. Chaffard remarked that he had treated a case resembling in many points that of his colleague. The heart had lost all its rhythm but both bruits were distinctly present. The treatment was very active—a cold bath every three hours, ice to the heart in the intervals, subcutaneous injections of sparteine (one grain to each injection) and alcohol and champagne.

M. Hayem said that the disappearance of the first bruit of the heart was very rare and in any case he had not seen a case of it. On the other hand, irregularity of the cardiac rhythm in typhoid fever was very frequently followed by death. In such cases he was not a partisan of cold baths ; or at least he employed them very moderately, and injected cafeine.

M. Nélaton read a paper on the treatment of

Fractures by Suture of the Bones

at the Surgical Society. In two cases of fracture of the clavicle the displacement was very great, and extravasation of blood was considerable. The seat of the lesion was laid open, and when the clots were removed, both fragments were sutured. The patients made excellent recoveries and without any apparent deformity. Fractures of the humerus and the femur were similarly treated with success. This method gave also an excellent result in a case of fracture of the tibia in which redution was rendered impossible by the interposition of one of the muscles.

TWO INTERESTING LAW CASES.

An action for damages has just been tried in one of the Paris courts which perhaps is unique of its kind. A gentleman suffering from anæmia of a very hopeless type was advised by his medical attendants to submit to the operation of transfusion, and having consented, his gardener volunteered to supply the blood. Consequently transfusion was performed, and to the great benefit of the patient, who recovered completely after a short time. However, some time afterwards the gardener fell ill, and attributed his condition to the sacrifice he made for his employer. He accordingly brought an action against him for damages claiming the large sum of 60,000 francs or nearly two thousand five hundred pounds. The court ordered an independent medical examination of the case, but in the meantime the man died, that is to say, two years and three months after the operation. The autopsy proved that the gardener had succumbed to a carcinoma of the stomach, and the doctors gave their opinion that the malady was not affected by the transfusion. However, the widow continued the suit, and last week the Court dismissed the case with costs against the plaintiff.

The second case was that of a woman who died last year at Sarran (Aveyron) in advanced pregnancy. The priest who assisted her in her last moments, persuaded one of the persons present to practise on the corpse the Cæsarean operation in order to save the child, or at least to baptise it. The operation was performed, but with a negative result as regards the child as it was taken out dead, but the authorities heard of the matter, and the operator was prosecuted for, not being a qualified surgeon, performing an illegal operation. The man was fined the maximum penalty—15 francs!

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, June 22nd.

THE CHOLERA.

THE cholera has already made its appearance in two places on the frontier, first at Myslowitz, on the Upper Silesian-Russian border, where it was introduced by a female tramp. She passed the night at a house where she was taken ill and infected six other people. Of the seven who caught the disease, six have died. As measures were at once taken to arrest the spread of the disease, and as no other cases have occurred, it is hoped the little epidemic is stamped out. A more dangerous gate of entrance to the disease is afforded by the river Weichsel with its river traffic from the bordering Russian Government District of Warsaw. At Schillno, the place where the Weischsel enters Russian territory, a Polish boatman took the disease, and then others promptly contracted it from him before the proper notification was forwarded to the authorities. Other cases have occurred at Plehnendorf. Military surgeons who have gone through the prescribed courses of bacteriological instruction have been appointed to guard against the spread of the contagion.

The disease has also thrown a larger amount of work than usual upon the Imperial Health Office, and to enable it to keep abreast of the work, two new members have been appointed. Both have previously acted as assistants in the same office. The two new members are Dr. Paul Kübler, and Staff-Surgeon Dr. Edger Wutzdorff.

On the 30th ult. the discussion on Landau's paper on

THE TREATMENT OF PELVIC ABSCESSES

took place. Hr. Veil did not think it mattered much whether suppurations in the pelvis, uterus, tubes, or ovaries were attacked from above or below. The more recent the disease the more suppuration was found. If one could wait in such cases they healed, and a tube that was still permeable might yet become healthy. When the suppurative process had not occluded the tube, extirpation of it was unnecessary. Occasionally serious disease followed the operation, but it rarely proved fatal. These cases were the best proof of the possibility of recovery, for it was not infection at the operation, but an exacerbation of the catarrhal disease in the tubes that caused the illness. In ten of his cases, therefore, he did not think the operation called for. In three of the cases there was abscess in the neighbourhood of the tube, and such diseases recovered without mutilation if protection from renewed infection was afforded sufficiently long. The cases also that burst into the bladder were also curable in other ways. The most serious case was one of puerperal pyæmia. If an autopsy were made in such a case four to six weeks after the commencement of the disease, the whole pelvis was found filled with abscesses. But women suffering in such a way generally pulled through, and we were only justified in performing mutilating operations when recovery could be brought about in no other way. He did not think any gynæcologist would follow Landau. He held the operation was only indicated in the rare cases of pyosalpinx bursting into neighbouring organs, or into the bowel. The operation from outside had the advantage that the manipulation could be overlooked. It was possible that only one tube or one ovary might be found diseased, and for these cases it was more suitable that the locality should be rendered visible.

Hr. Körte urgently recommended Landau's method.

Hr. Mackenrodh said that in judging of the new operation it was important to determine whether the abscesses were intra-peritoneal or in the parametrium. The latter all recovered with the curette and iodoform gauze tampons. The intra-peritoneal abscesses rarely healed. What did total extirpation do in such complicated cases? The abdominal cavity must be opened, the uterus removed, the pus flowed into the abdominal cavity, finally the adnexa were dragged out and the woman left the place without any genitals at all. In 600 laparotomies performed by himself, the speaker had only met with seven complicated cases. His cases of pyosalpinx were thirty-one in number. Not one of these patients died, they all retained their uterus, and with the exception of two they all retained one ovary and still menstruated. It was always a very doubtful thing to rob a woman during her sexual life of her organs of menstruation, for women so operated on were generally worse in the course of a year or two than they were before. We were only justified in total extirpation when the adnexa were converted into closed sacs. In extra-peritoneal abscesses he had first of all opened, curetted, and drained, and the communication with the tube sac had closed. In no case were virulent germs found in the tumours, and this explained the reactionless course of recovery. Statistics far greater than his own were also in favour of laparotomy. In separation of adhesions, the intestines must be wounded in many cases, and laparotomy would then have to be performed to save the patient, and when a patient did recover under such circumstances, it was due simply to the skill of the operator. The operation should only be performed in carefully-selected cases.

Hr. Dührssen defended Landau's operation.

Hr. Bröse believed that symptoms would often remain in spite of removals of pyosalpinx, and cleaning out the uterus, as they depended on chronic peritonitis, which frequently could not be cured. There was no basis for fixing the principle that the uterus should be removed. To remove the uterus from prophylactic motives because it might again be infected with gonorrhœa appeared superfluous.

Hr. Gottschalk pointed out that Landau did not by any means go so far as the French gynæcologists, who would remove every pyosalpinx through the vagina. He himself passed the finger by the uterus, forcing a way, and making one cavity out of the different abscesses.

Hr. Landau, in reply, said he only practised the radical operation when the symptoms called for it. When lapatoromy offered a favourable chance it was performed. In cases that could not be reached from the abdomen, or treated by incision from the vagina, and which would otherwise be fit only for a hospital for incurables he performed his radical operation. Injury to intestine was no reproach to the vaginal method, for this often happened in laparotomy, and was sometimes unavoidable. The question could only be decided by experience. It was something Pharisaical to call extirpation of the uterus and adnexa barbaric and mutilating when the terms were not applied to removals of the adnexa without the uterus.

◆

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, June 22nd.

Cystic Fibro-Adenoma.

Class showed a case to the Medical Society of a woman, æt. 44, who had always been healthy, had borne four children, but had come to him a short time since concerning a swelling that had commenced about two years ago. On her first appearance the tumour was about the size of the uterus hanging between the extremities, a greyish colour with a fluctuating body in it about the size of a hazel nut. By passing a sound about 12 cm. into the cavum uteri it was evident that no inversio uteri existed. A double ligature was applied to the pedicle and a tumour of 1,600 grammes was removed. The lower part had an epithelial epidermic covering which indicated a long exposure from the vagina which had long been treated for prolapsus uteri. The tumour was suspended from the right side of the cervix.

Prof. Weichselbaum had examined the tumour before removal and was of opinion that it was cystic in origin with mucous contents which later had become involved in a stroma which it contained. From an examination of the literature of cases very few are recorded of such a size with such contents. One similar to this is described by Schatz as Fibroma Cysticum Diffusum et Kolyposum.

Kessler describes another as Myxadenoma Cysticum.

Ectasia of the Chyl Vessels.

Prof. Weichselbaum related the case of a man who had come from Hofrath's Iraschés wards with carcinoma ventricali, numerous metastasis in the lymph glands as well as the ductus thoracicus. The abdomen had been twice tapped for ascites, which gave on both occasions a yellow-white milky fluid in large quantities (Ascites Chylosus). The post-mortem revealed a white network of vessels over the mesenteric glands and the serous covering of the stomach. The upper part of the ductus thoracicus was surrounded by the carcinoma, the lumen almost closed, more particularly at the cysterna chyli. The vessels which supplied the cysterna were thick, containing the same white-yellowish fluid surrounded by bands, this condition extended to the duodenum and jejunum, which may readily account for the ascites chylosus.

Two other cases of ascites chylosus are recorded in literature produced by carcinoma in the neighbourhood of the ductus thoracicus whose primary centre was carcinoma of the stomach.

Prof. Weinlechner recorded the case of a young woman who had been under his care with several lymph ectasia on the left leg and vulva. The epidermis was white and elevated and the discharging fluid flowed in large quantities, of a yellowish-white colour. The final destiny of the girl he was unable to record. In laparotomy he often met with highly injected chyl ducts. On one occasion he was under the necessity of tying the vessels.

Trepanation.

At the Geselschaft this week, Prof. von Hacker gave the history of an operation he performed on a young woman, æt. 19, who had been several times previously operated on for otitis media suppurativa in the special departments for aural treatment without any successful results. The symptoms present, according to Hacker, were severe headache, more particularly the left side of the head, vertigo, and sudden attacks of unconsciousness, elevation of temperature, shivering, hyperæsthesia of the trigeminal branches, cramp and convulsive movements in the right facial and accessorius nerves which passed over to both upper and lower extremeties. These phenomena led him to the conclusion that an abscess had formed or was forming in the brain. Trepanning the cranium was undertaken on the 24th of January to relieve the patient, and an opening made into the middle cavity of the cranium. The dura mater was found vaulted, no pulsation, and having a greenish-grey appearance. On puncturing this a large quantity of cerebral spinal fluid was emitted, but no pus. A small quantity, apparently from the sinuses of the posterior and anterior cavities, but no trace of any abscess having existed. It is noteworthy to mention that the condition of the patient immediately began to improve after the operation, while all the cerebral symptoms disappeared. The results appear to have justified the operation, as the opening of the tense dura mater relieved the pent-up fluid, as there is little doubt meningitis would have been the consequence. The discharge from the ear still proceeds.

Prof. Politzer remarked that this patient had been under his care for several years past. When she came first under his observation she suffered from chronic inflammation of the middle ear, and in spite of all energetic treatment became worse, with purulent discharge, which gave indubitable assurance that caries of the small bones was the cause of resistance, for which he operated four years ago and extracted the malleus. On this occasion it was observed that a large area of the tympanum was destroyed and the aural function useless. After the operation the pustular discharge did not cease, but appeared to burrow further in producing caries in the mastoid process, and six months later he opened the antrum by trepanning. Still the pus did not cease.

Three years later she returned with a new appearance of aggravated headache with confusion in the head, for which he proposed the radical operation by Küster's method. After removing the posterior muscles of the ear the mastoid process was again opened and the posterior and upper wall of the meatus auditorius was chiselled out; all the remaining wall of the tympanum and the interior granulating surface of the middle ear was cleared out with the hope of checking further invasion. Notwithstanding this heroic endeavour, the discharge still existed. Eleven months later she returned to the clinic with severe headache and greater discharge from the ear, seemingly issuing from the middle ear, which on examination was found to be filled with a mass of cholesteatoma that was speedily removed, when the meningeal symptoms disappeared.

He considered this a blemish in both Stake's and Küster's method, as the invasion of the epidermis from the external meatus of the ear easily gained access and favoured the formation of cholesteatoma. The only explanation he had to offer in this stubborn case was the impracticable access to the rapidly-advancing morbid condition. The bone being full of air spaces, it is clear that all disinfecting agents could not reach beyond the infecting centres and arrest the process of septic change, which frequently makes its way along the pyramids stretching up beyond the labyrinth capsule, where it is impossible to reach by means of instruments.

This case is both interesting and useful to show that such an operation can be of great service in the treatment of middle ear cases, where cerebral symptoms often supervene with persistent otorrhœa and danger to life through complications arising, as meningitis, sinusphlebitis, and pyæmia.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Excision of Knee—Peculiar Condition.—Mr. Rose operated on a man, æt. 20, who had been a soldier, and who had suffered, according to his own account, from syphilis, for which he had been in hospital three weeks. The knee was all right to within about seven months ago and the general health good; he had noticed a difficulty in bending the knee, and had experienced great pain of a racking character which was much worse at night. Hot fomentations had been tried but the knee got bigger and the pain was not relieved; after this Scott's dressing had been applied. About three months before the present operation the joint had been aspirated and eight ounces of greenish coloured liquid with a little blood taken away; this, however, did not seem to diminish the swelling and the pain at night continued; blisters were subsequently applied and the joint again aspirated, about two ounces of liquid being removed on this occasion; after this for five weeks a three per cent. solution of carbolic acid was injected into the knee every morning and the joint became easier. The patient had always been able to move the joint more or less without much pain. At the time of his coming to King's College Hospital the knee had become very large, the patient had lost weight considerably, there was only a little starting pain at night, the swelling extended up the thigh, the leg was emaciated and the patella dislocated outwards; there was no tenderness. After cutting in to the swelling to explore it Mr. Rose excised the joint in the usual way remarking that he had never seen a similar condition; there was no pus, no ulceration of the cartilages; the synovial membrane was converted into a firm, semi-translucent leathery tissue with here and there spots of hæmorrhage. The section of the bone appeared healthy though soft. He said that he was determined to give the patient a chance by excising instead of amputating on the supposition that the disease might be syphilitic. It was certainly not malignant and he did not think it was tuberculous. The whole synovial membrane was really replaced by the above mentioned tissue.

GREAT NORTHERN HOSPITAL.

Intestinal Obstruction—Left Inguinal Implication. Stricture of Ascending Colon Resected from a Right Lumbar Incision.—Mr. Herbert Allingham operated on a man, æt. 66, who had been admitted with intestinal obstruction of some weeks duration. The abdomen was greatly distended and the patient vomited constantly. Nothing could be felt by rectal examination Mr. Allingham opened the abdomen in the left inguinal region and found the sigmoid flexure empty, he then enlarged the incision and introduced his hand into the abdomen. The cæcum being felt distended search was continued up the ascending colon and just opposite the right loin a stricture was felt. Mr. Allingham accordingly sewed up the left inguinal incision, turned the patient on to his left side and incised the right loin, opened the peritoneal cavity and pulled the ascending colon with its malignant structure from the wound. The gut was secured above and below the stricture and the latter was thoroughly cut away. The distal end of the bowel was carefully stitched up with Lembert's sutures, cleaned and dropped back into the belly. Into the proximal end of the divided gut a Paull's tube was fixed and the gut secured to the loin. Through the Paull's tube the bowels acted freely. Mr. Allingham said at the time of operating if the patient recovered from what he had done, later on he would attach the cæcum to the sigmoid flexure, and still later on sew up the opening in the right lumbar region. The patient at the time of the operation was too bad to stand both the resection of the stricture, and the suturing of the ends of the gut together.

It is interesting to note that the patient has done well.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Hydronephrosis—Nephrectomy.—Mr. Owen operated on a girl, æt. 11½, who had been ill on and off for nearly two years, and had lately been treated by her doctor outside the hospital for typhoid fever. She had occasional attacks of vomiting, and a few weeks ago a swelling had been noticed in the left side of the abdomen. The tumour bulged forwards from the left renal region towards the middle line, and even to the right of it, and extended downwards into the pelvis. Though it gave rise to a dull percussion note between the last rib and the iliac crest, it did not bulge there. There was resonance above, below, and to the left of the tumour, but none in front of it. A two-inch incision was made in the middle line below the umbilicus, and on the peritoneum being incised the empty descending colon was at once recognised upon the front of and adherent to the tumour, sure evidence of the post-peritoneal origin of the cyst. About two pints of a sherry-coloured fluid having been drawn off by a trocar, an attempt was made to enucleate the tumour, but as this could not be safely effected through the small opening, the incision was enlarged downwards. The vessels and the ureter were tied with silk, the cyst was removed, and the wound was closed with a continuous silk suture. Mr. Owen then demonstrated the cyst; it was growing from the inner and anterior aspect of the kidney. What was left of the renal tissue was a thin, lobulated mass, which was estimated at being about eight inches long. Examination showed that the ureter was not in the least dilated. Mr. Owen remarked that the lobulation of the kidney was suggestive of its early developmental condition, and he was inclined to think that the nephrotic dilatation was of long standing. He was satisfied that removal of the entire gland-tumour was the simplest and most satisfactory treatment.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JUNE 27, 1894.

DEAD LETTER LAWS.

The maxim which tells us that a chain is no stronger than its weakest link is specially applicable to the round of sanitary administration. On the whole, the state of the law as regards public health matters is fairly well up to the level of recent knowledge. At the same time one cannot doubt, so swift is the onward march of the sanitarian, that the state of affairs which may be to-day accepted as tolerable would a generation later be looked upon as unspeakably bad. But any set of laws, however good and wise, without a proper machinery of administration, is certain to drift sooner or later into the helpless condition popularly known as a dead letter. First of all it is necessary to have an earnest and enlightened local authority, ready to administer the law without respect of persons, and to steer a middle course between false economy on the one hand and rash expenditure on the other. Then comes that important and specially educated official, the medical officer of health, on whose zeal and discretion the well being of a district so largely depends. By the inherent conditions of his post, however, he is bound by the decisions of his master, the vestry. It is obvious that a progressive medical officer and a backward board cannot pull together for any length of time. Then the medical officer may find himself seriously hampered by having a staff of inspectors, either too scant in point of numbers, or individually inefficient and untrustworthy. Under the present system it is notorious that a greater or less amount of bribery takes place among the small fry of officialdom. Nor can a medical officer hope for a proper control over inspectors whom he can neither select nor dismiss at his own discretion. Indeed, in one of the London districts the public is constantly entertained by the spectacle of a sanitary inspector giving evidence against his superior officer. The weak spots of administration which have been so far noted could for the most part be set right with a little legislative readjustment. So, too, could the obviously out of date condition of appointment still surviving in many London and provincial districts, namely, that which allows the medical officer of health to engage in private practice. If any such official were to attempt to fulfil his multifarious duties with anything like thoroughness he would soon find himself in despair at the impossibility of the task. Indeed, it has long been an accepted article of the social progressist creed that the "half-time" man is an anomaly, and in sanitary life especially he is altogether out of balance with the vast and increasing importance of his department to the welfare of the community. The way in which good laws may be shelved and rendered worthless could not be better demonstrated than in the case of the London bakehouses. Plenty of means, apart from special trade legislation, exist in the provisions of the Factory and Workshops Act for the purging of such insanitary premises. The evils of the underground bakeries are conspicuous; in the majority of them, for instance, proper ventilation is structurally impossible. The places are inspected often enough, but there is no common standard of wholesomeness fixed and recognised by the authorities. As a rule the vestries are unwilling to prosecute, or in the event of a fine being imposed, they decline to repeat the prosecution. The consequence is that a baker may often carry on his trade in a place proved to be destructive to his workmen by paying a simple fine of forty shillings. It is only natural that Medical Officers of Health should be reluctant to urge on prosecutions which are likely to prove thus futile. Under these circumstances the Local Government Board lately issued a circular to all local authorities in London pointing out that they possessed under existing legislation ample powers for dealing with insanitary bakehouses. How far that memorandum will be acted upon remains to be seen, but as it stands, the whole affair forms a pretty object lesson in "dead letter" law. If the Local Government Board were possessed of more vitality and public spirit its services in enforcing the administration of existing legislation would be invaluable. In the opinion of many thoughtful observers the creation of a central independent body, *sans peur et sans reproche*, is essential to secure efficiency and economy in the administration of public affairs. The London County Council is rapidly extending its powers, and although it has done undoubtedly good work, its future career will need to be sedulously kept up to a pure standard by the zealous watchfulness of the democracy to which its creation is due.

◆

THE COMING ELECTION AT THE COLLEGE OF SURGEONS, ENGLAND.

ALTHOUGH the candidature of Mr. A. T. Norton has been lost to the Association of Fellows, and has deprived the forthcoming election at the College of Surgeons, England, of much of its interest, it is nevertheless only fair to say that the inadvertent mistake into which he fell of sending in his application too late was one which might have occurred to any candidate. In this connection we might reasonably ask why is it that the latest date on which the application form must be returned to the College is not printed on the form itself? For what earthly reason does the date only occur on a detached communication from the secretary, which is so apt to be mislaid and cast aside after having once been read. We would strongly urge the Council to have the necessary dates with respect to the application form printed on the form itself, so that no error may arise in the future. But now that the Association of Fellows has lost its candidate, how does it stand in regard to the other aspirants for seats on the Council? In our issue last week we hinted that it would probably decide to favour the return of Mr. Harrison, Mr. Marsh, and Mr. Davies-Colley; and just after we went to press the annual meeting of the Association was held, at which a resolution was unanimously passed pledging the Association to do its utmost to secure the election of these candidates. The reason for this step was explained at the meeting. Mr. Harrison and Mr. Marsh are old Councillors; both are popular; and while the former was materially assisted into the Council at his first election by the members of the Association, the latter has so far done nothing to openly oppose the reform movement in the Council. The Association have, therefore, and we think wisely, determined to accord them its support. But with respect to Mr. Davies-Colley, how does the matter stand? Mr. Colley's name has been associated with an opposition clique which had hoped to scatter the influence of the Association to the four winds of heaven, and it might seem upon these grounds somewhat inconsistent on the part of the Association to pledge itself to do its best to secure his return. In truth, however, although Mr. Colley has nominally identified himself with the clique which prides itself in having no policy, Mr. Colley himself has in a communication to the Association distinctly avowed himself in favour of obtaining a new charter—the last crucial point upon which the energies of the Association will be concentrated. Clearly, therefore, Mr. Colley is appealing for the suffrages of the Fellows with the definite object in view of assisting his constituents to secure that for which many of them have for long been striving. Under these circumstances, the Association has had no difficulty in recommending his candidature, and with the interest of the large medical school to which he is attached, in combination with the help of the Association, his return should be almost a matter of certainty. The only other candidate concerning whom any remarks need be made is Mr. James Hardie. Mr. Hardie occupies a unique position; he may be said to be a unique candidate. Apparently his claims to the distinction for which he is aspiring are based upon the fact that fortuitous circumstances have made him the senior surgical representative at a provincial school whose representation on the Council has just terminated with the resignation of Mr. Lund. But there is one amusing element in his candidature which it is impossible for us to overlook. Certain of his friends have issued a circular to all the Fellows, urging his claims upon the constituency, and among other things which they are good enough to say of him we find the following: "We have laid no stress upon any of the questions which are generally considered as 'college politics,' *feeling that most of these are of no vital importance* . . . . We prefer to place our trust in a man of known breadth and fairness of view, unfettered by pledges to support any special line of action until he has attained from actual service upon the council the experience necessary to form a just estimate of the best policy of the Royal College of Surgeons." The italics are ours. We wonder what Mr. Hardie's friends would say if a political candidate were to come to them with this programme and to seek their suffrages for a seat in the House of Commons! Practically, it is equivalent to saying, "I know nothing of the working of the post to which I am seeking to be elected; I am entirely ignorant of its duties; if you elect me I shall be perfectly useless until I find out by experience what those duties are; I admit that my ignorance is perfectly inexcusable inasmuch as I could easily have made myself acquainted with all those important questions about which so much discussion has been taking place. Clearly, therefore, I must be absolutely unqualified for the honour which I am asking you to help me to attain," nevertheless I want you to elect me! In a few words, this is the aspect from which Mr. Hardie's candidature, as advocated by his friends, should be viewed, and we cannot believe that any Fellow who has the interests of the College at heart, could overlook the absurdity of the position in which Mr. Hardie has been placed.

◆

ELECTION OF EXAMINERS AT THE ROYAL COLLEGE OF SURGEONS, IRELAND.

THE Council of the College has given notice of its intention to elect second examiners to examine in the subjects with which the College has to do in the Conjoint Examinations with the Apothecaries' Hall. For many years past it has been the rule, for all Examinations of the College, to appoint two examiners in each subject, each of whom conducts the examination alternately, the unemployed examiner being supposed to watch the examination, form his own judgment as to the answering, and record, by mark, his independent verdict. This, we say, is the theory of the system;

but, as a matter of fact, the assessorship function of the unemployed examiner has always been a matter of form. There have been, no doubt, many examiners who have acted up to the theory; but it is notorious that, in the great majority of instances, the unemployed examiner or accessor, simply rested himself until his turn came again—took little notice of the examination of his colleague, and contented himself with recording the same mark as his colleague. We apprehend that the same observation applies all the world over, and the assessorship system in England and Scotland is not a wit more valuable as a test of the candidate's knowledge than anywhere else. But the effect of the assessorship theory, and of the system based upon it, has been to burden the Colleges with the cost of two examiners when one could do the work—in other words, to double the cost of examination. Now it happens that the Irish College of Surgeons has recently found it necessary to curtail expenditure, and it has reduced the examiners' fees by one-half. This was a heavy loss to the examiners under the Conjoint Board of the Colleges of Physicians and Surgeons, but as the number of candidates under this conjunction is large, the loss was accepted by the examiners with some grumbling. For the examiners under the Apothecaries' Conjunction and the College of Surgeons, the matter was different, because the number of candidates was very small, and the examiners got practically nothing for their work. It was, therefore, agreed by the College of Surgeons that no second examiners should be appointed, but that the not very important function of assessor should be discharged by the examiners of the same court in other subjects. For instance, the Examiner in Surgery assessed the examinations of the Examiner in Anatomy, the Examiner in Physiology assessed those of the Examiner in Pathology, and so on. The working effect was that the assessorship was most effectually performed by skilled and experienced examiners, and the fees paid to them for their work were not reduced. This was one of the "mare's nests" discovered by the Visitors from the Medical Council, and made the occasion for a virtuously-indignant diatribe against the Conjoint Examinations of the Irish "College and Hall." They were horror-stricken at the iniquity of allowing a surgeon to assess an anatomist, or a physician to assess an obstetrician, and the Irish College has yielded to their demands, as, indeed, it would have yielded to any demand, however ridiculous, at the present time. The second examiners will be elected on the 2nd of July. It would, we suppose, be asking too much to beg the Medical Council and its Visitors to come down from their stilts for a moment to consider whether assessor-examiners, as at present worked, are of any use whatever. Practical questions like these have no place in the programme of the Medical Council, and so we must perpetuate this and many other anomalies to please our rulers.

◆

We are glad to note that Mr. Henry Morris has been appointed to the vacancy in the Court of Examiners of the Royal College of Surgeons, England, created by the resignation of Mr. Treves.

Notes on Current Topics.

Her Royal Highness the Duchess of York.

The safe delivery, on Saturday last, of Her Royal Highness the Duchess of York, of a son, at White Lodge, Richmond Park, is an event which has naturally not failed to send an emotion of pleasure and loyalty through the realm, and, beyond the realm, to every portion of Her Majesty's Empire. In common with other loyal subjects of the Queen we offer our loyal and respectful congratulations. That another Royal Prince should have been born in the direct line of succession is a matter which will especially appeal to the nation as a subject for universal rejoicing. So far as the medical incidents of the accouchement are concerned, we understand that Dr. John Williams was summoned on Saturday morning at three o'clock, and at ten o'clock on the evening of the same day the birth of the Royal Prince took place. As the public Press has reported, the progress of Her Royal Highness to convalescence has been perfectly satisfactory, and the health of the infant Prince continues good.

Kleptomania.

In the latest text-book of medicine published in America under the editorship of William Pepper, kleptomania is classed under the heading of periodical insanities, while Dr. Clouston ascribes it to want of inhibition, weakness of inhibitional power, stating that he has never seen a case which did not present other symptoms than the mere thieving propensity. A Justice of the Peace for Cumberland and member of several public bodies in the district of Silloth, was tried last week at Dumfries for theft at a sale, and the plea of "insane impulse" put forward on his behalf. Dr. Charles M'Culloch, the medical attendant of the accused, gave evidence to the effect that he was dyspeptic, and had during the last few years become despondent, fidgetty and irritable in his manner. Since the charge had been preferred against him he had shown witness two boxes filled with things appropriated from other sales comprising old pistols, billiard balls, and other articles of little value. Dr. M'Culloch thought that in view of these facts the accused might be looked on as a sufferer from a form of moral "insanity" appearing as kleptomania. Dr. Littlejohn, of Edinburgh, who had examined the accused, was then called on to give his opinion. He stated that during forty years' experience he had known of twenty-two cases of kleptomania in the police-courts, and that in this case the accused did not seem to grasp the gravity of his position at all, and was childish in his manner. Kleptomania was due to a peculiar degradation of the brain, and was usually a prelude to something worse. The Sheriff, however, found that, as there was only one text in the law, to wit, whether the person knew the nature of what he was doing, knew that it was a wrong thing to do, and despite knowing that he did it, the accused was guilty, being of opinion that he knew the nature of his act by the pains taken to conceal it. He accordingly fined him £10. The case will probably be appealed. The idea because a person steals a thing cleverly and with pains he cannot be insane may be legally true, but is certainly not medically so, for some of the most pronounced lunatics steal with great ability. The case shows the necessity for more defined legislation with regard to that section of moral insanity different grades of which produce most of our criminals.

A Comparison and a Difference.

The newspapers last week were absolutely teeming with the reports of the Royal function which took place at St. George's Hospital in connection with the presentation of the testimonial to Dr. Dickinson. To-morrow (Thursday) a friendly gathering will take place at St. Bartholomew's to do honour to its late deservedly popular and distinguished senior physician, Dr. James Andrew. But under what different circumstances will this latter function be held in comparison with the wholesale pageantry under which Dr. Dickinson has retired from St. George's! Both Dr. Andrew and Dr. Dickinson did great service for the respective schools with which they were connected; both equally deserved some worthy recognition of their long years of work at the hands of their *alma mater;* both will be followed into their retirement with many memories of gratitude and respect on behalf of those who were their pupils. But while the friends of Dr. Dickinson were "fussy," and were successful in raising "a mound out of a mole hill," those of Dr. Andrew displayed a dignity and a respect for professional decorum which, it must be confessed, was only to have been anticipated from the authorities and staff of St. Bartholomew's Hospital, the traditions of which are so incomparable in this respect. The worth of a man is not to be estimated by the mere material value of the testimonial which his friends choose to give him. So far as Dr. Andrew is concerned, his appointment at St. Bartholomew's proved to be invaluable to the school. As a teacher he was unsurpassed, and no student who was fortunate enough to be chosen for work in his wards could fail to be impressed with his personality, his capacity for imparting knowledge, his friendliness in helping forward those who displayed an eagerness to learn. But if, without the flourish of trumpets, the presence of Royalty, or the "fuss" of a great public function, Dr. Andrew is allowed to enter upon his retirement, after the unostentatious presentation of his portrait to the Treasurer and Governors of the hospital, he may still derive consolation from the fact that this method of honouring his services could not have been more in accord with the decorum and dignity which the profession rightly demands should be observed on these occasions.

The Brentwood School Scandal.

The facts disclosed at the trial of Nurse Gillespie for cruelty to the infants under her care at the Hackney Union School at Brentwood are of a sufficiently startling nature. It appears that this woman, for at least eight years past, has pursued a course of systematic barbarity towards the helpless children under her charge. She made it a point of regular discipline to march the children about the room for an hour or more at a time, carrying baskets of clothes on their heads and clad only in their shirts. She dipped their heads in water and flogged them with broom-handles, frying-pans, or with any other object conveniently at hand. She would not allow the wretched children any water, so that they were compelled to lap up the rain puddles, or to use the water from the pans of the closets. She scourged the bare backs of her victims with bunches of stinging nettles, which were regularly gathered for her by a pauper assistant nurse. All this and much more was proved in evidence, and fully warranted the observation of Mr. Justice Day, that the case was a gross and frightful one. He also said that the existence of such a nursing inferno in a Government institution, with a large staff of officials and a skilled medical officer, subject to the supervision of a visiting committee, Poor-law inspectors, and a body of guardians, almost surpassed belief. His sentence of the full penalty of five years' penal servitude does not err on the side of severity, especially as the death of one of the children was proved to be largely due to the convict's abominable cruelty. This occurrence, together with the scandals which have been brought to light in many pauper schools of late, such as the wholesale poisoning at Forest Gate, and the outbreaks of ophthalmia on every side, are sufficient in themselves to raise serious doubts as to the efficiency of the Local Government Board. The whole Poor-law system demands a searching and independent inquiry, with much reform of a drastic nature.

Medical Certificates for Quack Medicines.

The editor of *Truth* is once again wielding his club, this time upon the newspapers that admit objectionable advertisements. He has instanced several journals by name, and a lame attempt at defence has been made by one of them, to wit, the *Weekly Times and Echo.* The editor of that paper states that he will insert no advertisements of a medical nature, or for adopted children, homes for children, &c., "without a written guarantee of the advertiser's respectability by some qualified medical man." On pushing his inquiries, the editor of *Truth* found that one particular nostrum advertised in the columns of his contemporary was certified by a medical practitioner in Southwark to be innocuous. The latter gentleman stated that a bottle of stuff was brought to him, which he did not analyse, but he satisfied himself as to its composition by the simple process of smelling and tasting it. He was of opinion that it could do no harm, and might possibly do good in some cases, whereupon he granted a certificate. There can be no doubt that this "medical gentleman," from Southwark has made a grievous error in certifying to the merits of a compound sold at an exorbitant price, as we are asked to believe, for the vilest purposes. We can only hope that his signature was obtained by misrepresentation. Certainly, the fact cannot be too widely known amongst medical men that they may be tricked into giving testimonials to persons engaged in a most abandoned and abominable trade. Moreover, if it be found that any practitioner knowingly countenanced the advertisement of such a nostrum his conduct should lay him open to severe punishment at the hands of the General Medical Council. The best traditions of the profession have had many a rude shock, but it may be doubted if any doctor could possibly sink to a lower level than when he poses as the associate of vendors of medicines that are intended for the use of the vicious and the criminal.

London County Council and the Asylums.

The London County Council has taken an important step with regard to the care of lunatics. It has adopted the suggestion of the Joint Committee of the Asylums, Industrial, and Public Health and Housing Committees referring to the control of asylums. The recommendation ran: "That it is advisable that the London County Council should have the control of all asylums both for lunatics and imbeciles in the County of London." If carried into effect this will mean the abolition of the Asylums Board, for the Council has already determined to take over the care of the infectious hospitals. The appetite for fresh duties on the part of the Council is simply omnivorous. In the course of the debate on the above resolution, Alderman Fleming Williams said the Health and Housing Committee thought they should undertake the inspection of lodging-houses, and be empowered to make regulations for the control of bakehouses, in order that they might be kept in a clean and sanitary condition. They also thought that if the Workshops Act was not to become a dead letter, the power of enforcing it must be entrusted to a central and independent authority. There appears to be a good solid groundwork of reason in the latter contention.

The Irish Poor-law Medical Superannuation Bill.

We have been obliged to delay reporting progress, or rather want of progress of this Bill, because we were not in a position to form a judgment of the chances of the Bill this session. Most of our readers are aware that, on the 5th of June, a deputation from the co-operating associations assembled in London to try to forward the Bill. The deputation consisted of Drs. Jacob and Oulton, for the Irish Medical Association; Drs. Donnelly and Knox Denham, for the Poor-law Medical Parliamentary Association, and Messrs. Manning (Rathdrum) and Atkinson, for the Poor-law Officers' Association. The object which this deputation had in view was, if possible, to achieve a general agreement of political parties to allow the Bill to proceed through second reading and into committee, or possibly to a Select Committee, where details might be threshed out. It was quite manifest that nothing save a universal agreement could effect this object, because it is not possible this session for any opposed measure to make any progress whatever, but the deputation had assurances from leaders and members of all parties which led them to hope that, possibly but not probably, such an understanding might be come to. We regret to say that this hope proved altogether illusory. We think it better, in the interests of Poor-law officers, not to say more than that certain parties, while presenting the most sympathetic aspect, and giving the most honied assurances, absolutely declined to give the Bill any quarter whatever. They would not enter upon any question of the details, although they kept the deputation in London for several days in the hope that the passing of the measure might be secured by concessions of detail; but when the second reading of the Bill was moved by Mr. Russell, it was at once stopped by Mr. Vesey Knox and others. The Bill may, we regret to say, be taken as dead for this year, and, as to its future, we see no reason to hope that any course can be pursued which will get it through the House until some day it is introduced as an opposed measure and put through its stages by votes of the House like any other measure. When that day comes, if ever, the whole influence of the co-operating associations will be wanted because—as far as we have any reason to know—no whittling down of the details would produce any effect in eliminating the persistent opposition by certain parties. We are confident that the large majority of Irish members of all politics are in its favour, but the opposing minority is quite enough to stop it.

Experiments on Soldiers' Diet.

The Army Medical Staff in Berlin are at present engaged in some novel experiments with a view to ascertaining what food is most beneficial for the soldier, and on what diet the best marching performances can be obtained. For the purposes of the experiments, a number of students from the Military Medical Academy volunteered their services, and during the past fortnight have accompanied a regiment of Guards in all its marching and field practices, dressed in the uniform of lance-corporals, and with the full field kit, doing full privates' drill and duty, and sharing in every fatigue. Under the supervision of a medical staff officer, these willing students are only allowed the prescribed rations, and are prohibited from procuring any other food whatever. Immediately after drill or practice they are marched to a service hospital for the purpose of having their physical condition officially inquired into and duly noted, and before as well as after each turn-out, their weight and pulse are ascertained. Some of the students are actually reported to have submitted to the application of the stomach pump in order to render the investigations more complete and trustworthy! Of course, enthusiasm in such a matter is to be commended, especially when the results are likely to prove of special importance. We wonder, if the facts having proved to be serviceable, will be regarded as State secrets, in the same manner as is the manufacture of certain munitions of war. Obviously the knowledge of a special diet under which soldiers were able to do their work satisfactorily and well would be of undoubted value, and most of all, perhaps, if it led to some diminution in the "*impedimenta*" in the commissariat and transport departments of armies in the field.

The Memorial to Surgeon-Major Parke.

Mr. Percy Wood, the sculptor to whom was given the commission to execute a statue of Surgeon-Major Parke, has already completed the model in clay, and a large number of those interested in the memorial paid a visit to Mr. Wood's studio last week for the purpose of seeing the statue. Surgeon-Major Parke is represented in African garb. His handsome head is thrown back, and the shirt is wide open at the throat. He rests his right arm on the barrel of his Winchester repeating rifle, and his left hand is laid on the right wrist. Under his left foot is the skull of an antelope, which gave the impression of being somewhat too fragile for the support of a big man's leg. The pose of the statue is easy and original, if not excellent, and the likeness could not be better. Mr. Wood is to be congratulated upon his work. In a short time the statue will be cast in bronze in Belgium, and in October will be erected on a site, still to be determined, in Dublin.

Princess Alix at Harrogate.

Sir Edward Sieveking is to be congratulated upon having drawn the attention of the profession to the merits of our English watering-places by the appointment of a committee of our leading medical society. One of its early fruits would seem to be that a member of our Royal Family has just gone through the "Cure" at Harrogate under the care of Dr. Oliver with very beneficial results, and we are glad to hear that her Grand Ducal Highness has much enjoyed her visit and her excursions in the delightful country around. This is probably the only instance in which a member of our Royal House has gone through a course of waters and baths at one of our British watering-places during the present reign, and it is to be hoped that this circumstance, as well as the work of the Royal Medical and Chirurgical Society will enable many for whom expatriation and long journeys are unsuitable, to derive benefit from the natural resources of our own islands.

A Popular Book.

Doubtless there were many who had misgivings about the success of a large work like "Quain's Dictionary of Medicine" when the undertaking was first projected; but, as we now know, such misgivings, however natural at the time, were quite uncalled for. The great work immediately after its appearance became popular, and its success has been phenomenal. No less than 33,000 copies have been issued since its publication in 1882, a fact which must naturally be a source of great gratification, both to the distinguished editor and the publishers. Under these circumstances no one can be surprised at the preparation of a second edition having been undertaken. At first, we believe, the idea was merely to reprint most of the articles, only making emendations and additions to the latter in cases where this was absolutely necessary. But it was soon found that this plan, although in some respects having much to commend it, was impracticable, owing to the advance of medical science. It was, therefore, determined to reset the whole work, thus allowing the contributors the opportunity of doing justice to their articles, and of incorporating in the latter the change of opinion in medical and surgical science which the past few years had brought about. The value of this policy is amply portrayed in the second edition of the "Dictionary" which appeared last week. The two handsome volumes of which it is now composed will enhance still further the reputation and fame of the work in which Sir Richard Quain has collected and edited the opinions of the foremost physicians and surgeons of the day on the subjects with which respectively their names and work are intimately connected.

Important Milk Decision.

The Bournemouth magistrates have lately given a decision which will affect not only the milk trade, but the authorities whose duty it is to administer the Adulteration Acts. One of the largest purveyors of milk in the town was proved by the analyst's certificate to have sold milk adulterated with 10 per cent of water. The defence was that the defendant could show he sold the milk in exactly the same state as he received it, under guarantee of purity, from a local farmer. Witnesses were called to prove this contention, and the Bench dismissed the case. The next problem for the Health authorities will be to find out how to get at the farmer. Surely some degree of responsibility must rest with the retailer in such cases. The plain man who wants practical justice rather than legal hair-splitting, might ask to have all parties to adulteration punished whether they are concerned as wholesale dealers, middlemen, or retailers.

The Spread of Small-pox by Tramps.

Last week it was our duty to record the extraordinary way in which a tramp, notified to have small-pox, was sent from pillar to post in Rawtenstall, and finally found refuge in a neighbouring town. This week, the epidemic which we ventured to predict, is showing itself in the first-mentioned place. Four cases of the disease have broken out, and among them are the owner, his deputy, and a woman living at the lodging-house where the tramp slept a fortnight ago. The deadlock between the Rawtenstall Corporation and the Haslingden Board of Guardians which led to this scandal still continues. The guardians offered to compromise on condition that the corporation would isolate future pauper cases; but this the town council refused to do. It is time this unseemly wrangle should be settled, otherwise the interests and safety of the public will demand the prompt interference of the Local Government Board.

Meat Poisoning at Bingley.

The advent of summer weather has been signalised by a wholesale ptomaine poisoning which has taken place at Crossplatts, near Bingley. From the published accounts it appears that some potted meat was bought at a local shop by six families, and eaten for dinner. The food was partaken of by nineteen persons, who in a few hours were one and all attacked by symptoms of violent poisoning. A number of the sufferers had to be carried home from their work. Notwithstanding the severity of the gasto-enteric symptoms none of the cases have so far proved fatal. Last summer was distinguished by the number and severity of meat poisoning cases. It is time that the question was taken in hand firmly. One is glad to recall that last year a butcher who knowingly sold the meat in one fatal case was convicted of manslaughter.

Insurance Touts.

We may issue a word of warning to medical men, especially those not long in practice, with regard to the methods in vogue in some of the transatlantic insurance offices. Cases have come to our knowledge in which young medical men have been induced to insure their lives, or to propose doing so, by the promise of all the company's cases afterwards, and in which on inquiry several practitioners in the same town have been thus approached. The insurance having been effected, the insurer, sanguine of a modest increase to his income, too often finds that the company has already a referee to whom the examinations are pledged; or that, if he does get a stray case, his premiums far exceed any pecuniary benefit obtainable.

Railway Microbes.

The Russian Government recently instructed the Board of Public Health to take a census of the microbes contained in the sweepings of railway carriages. The results are really somewhat startling, for while the dust from first class carriages yielded 16,000, and the second class dust, 34,000 germs to the square inch, that from the third class *wagons* (properly so-called) gave 70,000 bacteria to the square inch. There is every reason to believe that a similar examination carried out in respect of the dust in the carriages of the London underground railways would prove even more prolific, and the time is, let us hope, not far distant when the railway companies generally will be constrained to provide far greater cleanliness and salubrity than they at present think necessary.

Odium Medicum.

A medical pamphlet offered to the public at the modest price of sixpence, is being noticed by some of the lay newspapers. It is from the pen of Dr. P. Gowan, late private physician to the King of Siam, and is entitled "The Painless and Successful Treatment of Cancer without Operation, with an illustrative case." It is said to advocate the non-surgical treatment of the disease. In the preface Dr. Gowan explains that he is undertaking the publication himself "at the risk of incurring the *odium medicum*" as the paper had been previously rejected by a newspaper. From this statement it is evident that the writer has in a deliberate manner run counter to the traditions of the profession as to the desirability of issuing to the general public monographs on surgical and medical subjects.

At the annual meeting of the Chelsea Hospital for Women Dr. Fancourt Barnes said that there was no doubt that the hospital was to a certain extent under a cloud, but in his opinion it was not a very dark or extensive cloud, and would soon roll away.

Mr. Gladstone is still making favourable progress, and time is gradually effecting improvement in the eye which was recently operated on for cataract. In the course of a week or more he will proceed to Scotland for change of air.

The Guy's Hospital Clubs Union now numbers 1,233 members, of whom more than 140 are old Guy's men, who long since left the hospital. "Guy's" always has been noted for the *esprit de corps* among its students, past and present.

Of the two boys who were indicted at the Exeter Assizes for manslaughter in connection with the accident causing the death of Dr. A. H. Twining, one was discharged, and the other was bound over to come up for judgment if called upon. Mr. Justice Wright stated that he deplored the fact that there was no suitable punishment which he could inflict in such a case.

The cost of being ill in London is greatly enhanced if resort be had to laying down straw in the street outside the patient's house, in order to deaden the sound of the passing traffic. A householder has just admitted that his bill for the straw amounted to £14, and he ascertained that this was quite an ordinary charge.

The Salters' Company invite applications for their recently instituted Fellowships in Chemistry and in Experimental Pharmacology. Each is of the annual value of £100, and tenable in St. Thomas's Hospital Medical School. On reference to the advertisement in another column it will be seen that applications should be made forthwith.

Special Articles.

THE ANTWERP EXHIBITION.

(*Concluding Report.*)

[From our Special Reporter.]

III.—Food and Dietetics.

Perhaps one of the most striking features at the Antwerp Exhibition is the abundance of concentrated foods, and the numerous attempts to perform at least part of the complicated processes of digestion outside the human mouth and stomach. Denaeyer's Peptonoids and Extract of Meat Company, of London, exhibit carefully prepared peptones and peptonoids for persons with weak digestive organs. Liebig's Extract of Meat Co. make a display of their *Extractum Carnis*, preserved meats, &c. There are several new comers in this direction: W. F. Schmoele and Co., of Antwerp, manufacture the "Cibils" extract of meat, which, though strong, is palatable. Then there is the Australian Meat Company, with their "Ramornie" extract of meat, strong and good, and a novelty, inasmuch as hitherto the majority of meat extracts are produced in South America. The Compagnie des Produits Kemmerich, of Antwerp and South America, have an imposing pavilion in the gardens, where they have brought together a wonderful collection of products, which embrace extracts of meats, meat peptones, concentrated bouillon, granulated and meat flour, prepared ox blood, besides preserved meats of all kinds. As far as our somewhat hasty examination and tests go, the Kemmerich preparations seem excellent. Brand and Co., of London, are well to the fore with their pleasant and easily assimilable essences of beef, veal and mutton, concentrated beef tea, meat lozenges, and other preparations for invalids and travellers. In the Military Section the *Service des Subsistances* of the Antwerp Division of the Army show samples of soups, meats, vegetables, and fats preserved in tins for campaign service; also biscuits. The tins contains 300 grammes each, and are opened by means of a key, for tearing off a soldered band, which does not come into contact with the inside of the tin or its contents. Quite a dozen exhibits are made by Belgian, French, German, Dutch, and Scandinavian firms of meat, fish, and vegetables in tins and glass bottles. For the most part these products are remarkable for their beauty of form and colour, and their delicacy of flavour, altogether a much higher order of specialities than the American goods of this description. Spinach sorrel, cardoons, cress, &c., are put up in bottles, and are "recommended by medical university professors" as blood purifiers and anti-scorbutics on travel, and for hot climates. Dr. R. Hundhausen, of Hamm, Westphalia, is among the exhibitors of foods for diabetics. His "Aleuronat" is a special preparation of wheat gluten, the albuminous flour making excellent flavoured bread with a slight admixture of ordinary flour, also "Aleuronat" biscuits. The flour itself contains from 80 to 96 per cent. of vegetable albumen, and the bread and biscuits from 55 to 66 per cent. of "Aleuronat." Another preparation for diabetic patients is "Fahlberg" saccharine. "Farine Renaux," which is prepared at Duffel, is largely used in Belgian orphanages, children's hospitals, &c., for the feeding of infants. Dr. F. Van Battle, of the children's ward at the Malines Hospital, says that it is an excellent preparation, sufficiently rich in mineral substances, especially the necessary phosphates, and keeps well without chemical changes. In the Ecole Professionelle Ménagère cases of samples of foods are shown, also utensils for preparing and cooking foods, &c., special care being taken to illustrate methods of sterilising and cooking milk for infants. Ollendorff-Wilden, of Bonn, Germany, send a handy apparatus for cooking and sterilising milk. The milk is put in bottles with automatic gutta-percha stoppers, and these are placed in a frame in a tinned receptacle, surrounded by boiling water. The stoppers act automatically, allowing steam to escape. Chocolates and cocoas form quite a feature of the Exhibition, the Belgian and German preparations for dietetic purposes being of the highest class, though for sweets and confectionery the French are easily first. "Pates alimentaires," such as maccaronis, vermicellis, and other preparations of maize form another important group, and are largely used in orphanages, hospitals, other institutions, and the army. When well prepared they certainly possess considerable dietetic value, being nourishing, easily digestible, and readily cooked. Malt liquors take up the largest share of the space devoted to beverages. In the Belgian Section nine provincial brewers' associations make collective displays. The grains, malts, and ferments used seemed to be of excellent quality, and the hops, in great variety, are fine, aromatic, but with a peculiar flavour, which is not always pleasant to persons accustomed to British hops and some of the German varieties. The beers themselves are clear, sparkling, and have a low percentage of alcohol, and are altogether light, but generally with a decided bitter flavour. The moderate percentage of alcohol, the special preparation of the malts (there being but little solids in these beers), and the aromatic principles of the hops, combine to give these Belgian beers a high hygienic value in certain cases. They do not overload the stomach or greatly affect the brain, and while slightly stimulating, are tonic, and, owing to the small proportion of solids, do not encourage rheumatic affections. Most of the German beers belong to the same class. Antwerp is also one of the principal centres of the distilling industries, and there are numerous exhibits of alcohols, gins, &c. Though doubtless Belgium and Germany are the homes of potato and beetroot spirits, these are not represented at the Exhibition. There are fourteen Belgian distillers who send exhibits of alcohol, gin, &c., derived from high-class grains only. These products are generally well matured and free from objectionable admixtures and the toxic principles found in new raw spirits. In the British section, "Canadian Club Whisky" (Messrs. Hiram Walker & Son) is an interesting exhibit. This spirit is distilled from the best Canadian grain, and according to analysis contains of pure alcohol (proof spirit) 84·0, acidity due to volatile acids only ·042, dry extractive residue ·151, ash ·004. It has a pleasant flavour, and is soft to the palate. Its age and genuineness is guaranteed by the seal of the Canadian Excise authorities: an agreeable and safe spirit. Natural and artificial mineral waters are not neglected, and there are also a large variety of wines, but we have no space to devote to their enumeration. Medicinal and fancy drinks are numerous. On the Continent a vast amount of fancy spirits, and also of non-alcoholic syrups and fruit drinks are consumed. Tonics are in much demand. Among these we find the vermouth derived from the bitter wormwood, the pernicious absinthe, orange bitters, an "Amer Cresson," by Delleur, of Liege, a preparation from watercress, claimed to be tonic and anti-scorbutic.

We observed in the elegant case containing the exhibit of Wm. R. Warner and Co., arranged by their London agents, F. Newbery and Sons, that Ingluvin is there shown in the compressed form. The convenience of this improved method of administration will be at once evident to the practitioner. The exhibit also comprised a thoroughly representative assortment of the well-known products of the firm, such as sugar and gelatine coated pills, parvules, compressed medicines, elegantly-labelled pil-vases, *et hoc genus omne*. This firm seems to be all but ubiquitous, the award of a silver medal at the International Medical Congress at Rome having just been announced.

Scotland.

[From our own Correspondents.]

Glasgow University Court.—There was a large amount of business to be got through at the last meeting of the

Court; much was of a purely formal character, but many items needed careful consideration. The resignation of Dr. Phillips of his Examinership in Midwifery was intimated, and Dr. Samuel Sloan, Glasgow, was appointed examiner for the remainder of Dr. Phillips' term of office. Professor Simpson being incapacitated by illness from acting as examiner in the final professional examination in Medical Jurisprudence, the Court approved of an arrangement made by the Senate that Dr. T. K. Dalziel should take his place. A letter from Lord Kelvin was submitted, offering for the acceptance of the University the apparatus belonging to him which has been in use in the Natural Philosophy department. The secretary was instructed to express the cordial thanks of the Court to Lord Kelvin for his gift, which they accept, and, in further reply to his letter, to authorise him to make purchases of further apparatus, as he suggests, against the first grant of £100 from the Bellahouston trustees for this purpose. A letter from Professor McKendrick was submitted regarding the application of the Bellahouston grant of £400. for the purchase of physiological apparatus, together with an estimate which he had received, and authority was given to Professor McKendrick to carry out the proposals contained in his letter. The secretary submitted a letter from the honorary secretary of Queen Margaret College Students' Representative Council, drawing attention on behalf of the students of that College to the lack of practical instruction in botany for women students. The letter was remitted to the Queen Margaret Committee with power to consult with Professor Bower. The Court agreed to recognise the six months' course of physics in Melbourne University, and also the lectures of the following on the subjects specified, all qualifying for purposes of graduation in medicine in this University: A. W. M'Alpine, Edinburgh—Botany; William Russell, M.D. Edinburgh—Pathology and Practical Pathology; Francis M. Caird, M.B., C.M., and Henry A. Thomson, M.B., C.M. Edinburgh—Surgery; Augustus A. Matheson, M.D. Edinburgh—Midwifery; Alexander James, M.D. Edinburgh—Practice of Medicine; George T. Beatson, M.D. Glasgow—Surgery (systematic and operative). A memorial from the Professor of Materia Medica was submitted regarding the expediency of attaching the Professor of Materia Medica and Therapeutics to a hospital: the secretary was instructed to reply that the Court regret that they do not see their way to take any immediate action in the manner Professor Charteris indicates. It was reported to the Court by the secretary that he had received intimation that Ordinance No. 52 had been laid before both Houses of Parliament, and that a number of ordinances had received the approval of Her Majesty.

The Sanitary Deadlock at Leith.—An extraordinary state of affairs is alleged to exist in Leith by Dr. Allan Grey, Medical Officer of Health. He charges the sanitary inspector with incapacity, mismanagement, and want of method, with neglecting complaints received in regard to nuisances, failing to supervise the cleaning of the byres and lodging-houses, and with delaying to disinfect vehicles used for the conveyance of infectious cases and the houses from which the patients were removed. The inspector is to be allowed three days to answer the charges. It would not have been astonishing if Leith had been visited with a worse plague than that of small-pox.

DUAL NOTIFICATION AND THE DEATH-RATE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Under the above heading a so-called discussion has been going on in the *British Medical Journal* for some weeks past between a member of the editorial staff and myself. He has occupied *six* whole columns, and I, having occupied *two*, am informed that a further letter of little over a column in length, which I sent by way of reply, cannot be inserted for want of space! You have already been so generous that it is with no little compunction I crave a little further indulgence in order to set forth the facts which the *British Medical Journal* has burked.

I began by showing that my immediate friends (amongst whom I am proud to include yourself) and I were not the only ones to throw stones at the Notification Act; and I quoted from a letter which appeared in the *Lancet*, of June 9th, by Dr. J. Grey Glover, our direct representative on the General Medical Council, in which he says: "It is not to be wondered at that there is still much criticism of the notification system and even some doubts as to the utility of it. The enormous epidemics of notifiable disease through which we are passing are proof enough that it is not so efficient for prevention of disease as we should expect it to be." Earlier in the year, on February 3rd, the *Lancet*, in a leading article on the Metropolitan Asylums Board, said, "To demand increased hospital accommodation for infectious disease is surely to deny the efficacy of the Notification Act. Of what avail is notification if the number of infectious diseases is to go on increasing; if it is not on the contrary to be an ever-quantity? . . . . Certainly, so far, we do not seem to have experienced any such diminution of numbers. The infectious diseases have come upon us lately like a flood. . . . . These proposals and forecasts (relating to hospitals) are disappointing in the light of the Notification Act, and compel us to think that either the Act is very inadequate and evasible, or that it is not going to accomplish the result of curtailing the proportions of epidemics, as had been expected." Last year, in London alone, 56,425 cases were notified, and although the accommodation was severely strained less than a third of them was removed to hospital. During the first four months of the present year Mr. Wynter Blyth tells us that in his parish of St. Marylebone the cases of scarlet fever and diphtheria are more numerous still, the former by 48 per cent., the latter by 39 per cent.

The returns for 1892 and 1893 show that it is not in the large towns alone but in the country at large that the death-rates from notifiable diseases have increased, and this at a time when four-fifths of the population had become subject to the system embodied in the Act. But the large towns afford an excellent field for investigation, and in the tables which you kindly published on the 23rd May, I have shown how during twelve years, 1882-93, the twenty-eight large towns of England fared with and without notification. During the last four years, twenty-six of the towns were under the system which requires the medical man to notify independently, and of these, no fewer than sixteen increased their mean death-rates from notifiable diseases, on a comparison with one or other of the two preceding periods of equal length. Thus, in 1890-93, as compared with 1886-69, London increased its death-rate from notifiable diseases from 0 71 to 0·86; Wolverhampton, from 0·44 to 0·45; Birmingham, from 0·44 to 0·56; Hull, from 0·46 to 0·48; Cardiff, from 0·62 to 0·80; Bradford, from 0 57 to 0·71; Sunderland, from 0·56 to 0·90; Leicester, from 0·41 to 0·57; Halifax, from 0·52 to 0·69. Besides these nine, there were seven others (five of which were under the boasted system during nearly the whole twelve years, four of them quite) and these had a higher death-rate from notifiable diseases at the end than at the beginning, that is to say, in 1890-93 than in 1882-85. Thus, Plymouth increased from 0·48 to 0·65; Norwich, from 0·52 to 0·58; Salford, from 1·01 to 1·29; Manchester, from 0·83 to 0·98; Oldham, from 0·59 to 0·62; Bolton, from 0·49 to 0·70; and Huddersfield, from 0 35 to 0·42.

The *British Medical Journal*, without any sufficient reason, declined to consider the middle period of four years, and contrasted the third with the first alone. The towns comprised in my Group I (including London and ten provincial towns) were under no system of notification during the first and second periods, and since London did not appear to advantage from a notification point of view in the third period, its population, exceeding four millions, was consigned to limbo. But much was made of the ten provincial towns and their declining death-rate from notifiable diseases, little or no need being paid to the fact that by far the greater diminution occurred between the first and second periods, when these towns had no system of notification. Moreover, the attempt was made to show that Group III., comprising towns which were wholly under the system in question during the last eight years, had fared better than any. But I have taken the trouble to sift the matter a little further, and from the fourteen towns of Group III. (which in the first period was of mixed quality) have separated nine which from the commencement were under the so-called dual system. In my tables, they are numbered from 19 to 27 inclusive, viz, Manchester, Oldham, Leicester, Bolton, Blackburn, Derby, Preston, Huddersfield, and Birkenhead. In 1881, their combined population was 1,098,313, and their mean, annual death-rates from notifiable diseases in the three periods of four years each, were approximately, 0·765, 0·922, 0·704, showing no very great advance after all. The mean death-rate from notifiable diseases of Group III. in 1890-93 was higher than that of Group I. in 1886-89, when the latter was under nosystem, yet the density of the latter was to that of the former about as 40 to 27. I do not think I need say more.

I am, Sir, yours, &c.,

D. BIDDLE.

Kingston-on-Thames,
June 23rd, 1894.

A QUERY—IS THIS A CASE OF COVERING OR NOT?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the early portion of last year a metropolitan coroner, after receiving the evidence of an unqualified practitioner, forwarded to the proper authorities his notes of the case, into which he had been making inquiries The evidence established the fact that the witness had been for nearly *twenty years* carrying on in every way a medical and surgical practice as though he had a perfect right to do so. It was proved that he was known to the public as "Dr. ——," and that his name, in conjunction with that of some duly qualified practitioner, had been displayed on the front of the house in which he resided. There were a succession of these gentlemen, none of whom remained in the practice for any lengthened period. The coroner's action resulted in the Registrar-General instituting proceedings against a qualified man for falsely certifying in a case of death. The defendant who resided several miles away from where this practice was conducted, experienced the humiliation of being heavily fined at one of the police-courts, which apparently convinced him he had better disconnect himself from the unqualified practitioner, and thus the latter was left without support. It might be supposed that now the crisis had come and the man would be obliged to leave the scene of his labours, and this was probably the belief of the respectable practitioners in the neighbourhood. But he did not go.. And why? A qualified man, who had recently commenced practice a few yards from where the unqualified practitioner had carried on his business negotiated with him, and ultimately *took him into his own house to live with him*, thus enabling him to flourish to this day to the fullest extent, and apparently without any fear of unpleasant consequences arising thereby. I regret that as I grow older I am losing my confidence in so-called medical ethics; but I sincerely trust there are still some honourable practitioners who severely condemn any member of our profession, be he English, Scotch, Welsh, or Irish, who sanctions by his support anything resembling illegal practice. From a purely business point of view medical men naturally murmur against the injustice of having their bread snatched from their mouths by an unqualified person.

Now, Sir, have they not a legitimate cause of complaint against a qualified man who would act in the manner described? In conclusion, I would ask, Would or would not the General Medical Council consider the action of the qualified practitioner in this case reprehensible from a professional point of view.

I am, Sir, yours, &c.,

GENERAL PRACTITIONER.

London, June 17th, 1894.

◆

SIR GEORGE HUMPHRY.

THE profession generally will learn with great regret of the serious illness of Sir George Humphry, of Cambridge. The telegrams at the end of last week respecting the state of his health were such as to cause the gravest fears among his large circle of professional and other friends. Happily, however, the latest reports are more reassuring, and we trust that his progress towards recovery will be maintained.

THE CONJOINT EXAMINATIONS OF THE IRISH COLLEGE OF SURGEONS AND APOTHECARIES' HALL.

THE President and Council of the College of Surgeons last week resolved to give notice to the Apothecaries' Hall of Ireland of the determination of its conjunction with that body for examination purposes. It is not necessary for us at present to make any observation on the matter save to express our opinion that the Apothecaries' Hall has been very unjustly dealt with. Our sympathy with the "Hall" is, however, scarcely needed, considering that it has other resources besides conjunction with the College of Surgeons, and may yet find itself much more prosperous as a qualifying body under the altered circumstances than it has ever been or would ever be likely to be in association with the College. The decision of the College of Surgeons cannot legally take effect sooner than a year from this date, and it would be difficult to forecast what that year may bring forth. Considering that the effort of the Irish College of Physicians to extinguish its rival, though successful in the Council of the College of Surgeons, was defeated in the General Medical Council by 23 votes to 6, it appears most probable that the Hall will, on the cessation of the conjoint examinations, acquire and maintain an independent existence as does the English Apothecaries' Hall. In any case, the decision of the Council of the College is pregnant with the most far-reaching results to medical education and qualifying in Ireland, and may be the turning-point for a revolution which threatens the very existence of both the Colleges.

THE CHELSEA HOSPITAL INQUIRY.

WE understand that the inquiry into the so-called Chelsea Hospital scandal has now terminated, and the Committee is engaged in preparing its report, which will soon be ready for publication. The inquiry has been of a most searching nature, all the staff having been closely cross-examined by the representatives of the Royal Colleges of Physicians and Surgeons in regard to those cases about which so much public comment had been raised. In one sense the inquiry was not a public one, that is to say, the general public were not admitted to the meetings of the Committee, but all those who could claim to have an interest in the proceedings were permitted to be present. We shall look forward with interest to the report, and will deal with it fully at the proper time.

RECRUDESCENCE OF SMALL-POX IN DUBLIN.

WE regret to learn that the epidemic of small-pox in Dublin, reported by us the week before last, and which had passed away, has been followed by a further outbreak of the disease. The cases, which number ten up to the present, are provided for in the Hardwicke Hospital, under the assiduous care of Drs. Nugent and O'Carroll, and we understand that arrangements have been made, in case of an increase in the number of cases, for their reception in Cork Street Hospital. It is satisfactory to learn that, although some of the cases were of a serious type, they are all making favourable progress toward recovery. One of the patients, we regret to say, is Dr. Coleman, Physician to Jervis Street Hospital, who contracted the disease in the performance of his professional duties. We learn with much satisfaction that he is making all the advance towards recovery which could be expected.

◆

Literature.

SIR DOUGLAS GALTON ON HOSPITALS. (a)

THE author's avowed object in writing this book has been to place on record those principles which ought invariably to be followed in every good hospital. It is a work dealing with general principles, and without reference to special requirements. The questions are regarded from many points of view, and the author, in addition to his own mature experience, has consulted freely the various authorities in the several branches of this subject. In his preface he makes a statement which has much truth in it, and is not so well recognised as it ought to be, viz., that while hospital construction has developed much and departed freely of late years, from original types it is not always characterised by hygienic perfection of structure or a reasonable approach to it. Indeed, in some recent palatial buildings, simplicity and hygiene have been sacrificed to style and outward effect. It would appear as if in such cases the elevation and frontage were first designed and the wards and various hospital requirements blocked out to fit this elevation, instead of blocking out the hospital requirements first, and the elevation to correspond afterwards. The craze for a good outward appearance and style is one of the most lamentable idiosyncrasies of public boards, because it implies a desire for show rather than for usefulness. The first chapter of this work gives an interesting historical summary of the rise and development of the hospital idea. A curious and remarkable fact emphasised in this chapter is that our present system of hospital construction mainly owes its rise, in this country at least, to the experience derived from the wars of the last and present century, where large numbers of sick and wounded were collected together in extemporised hospitals. Sir Douglas quotes Dr. Brocklesby and other military surgeons who have shown that hospital huts and tents, in which the patients were exposed to unfavourable conditions from cold and wet, produced more numerous and rapid recoveries from wounds during these wars, and from the diseases incidental to camps, than the permanent hospital buildings then in use. Two important principles were here established, viz., the importance of fresh air and cleanliness. In the second chapter Sir Douglas defines a hospital: he defines broadly, and has regard not only to the primary purpose, the reception and cure of the sick, but also in the interest of the general community to technical school advantages, and purposes of scientific research. He further enlarges his definition by classification, and by laying down principles to start with in considering the form of the building. The work, then, as its title indicates, is conceived with a view to health, points of construction are incidental, the questions to be considered are site, movements and purification of air, warming, and lighting. These matters are treated of at considerable length, through several chapters, and then the author proceeds to illustrate the application of these principles in some of the best hospitals in this and other countries. Many other matters of importance are dealt with here, but enough has been said to show the author's purpose and how he has carried it out. The book is well got up, profusely illustrated, and, needless to say, is thoroughly well informed, and excellent reading. Sir Douglas Galton has here again proved himself a master of sanitation and hospital construction.

NATURE'S HYGIENE. (a)

THE appearance of a fourth edition of Mr. Kingzett's useful manual of Hygiene within a period of fourteen years is a sufficient testimony to the value of the teachings it contains; and no pains have been spared by its author to bring the latest issue of the work well on a level with the rapidly-increasing knowledge which modern scientific research has accumulated. Naturally a prominent position is allotted to the results of bacteriological research as bearing on the perfection of preventive methods, and the chapters wherein Mr. Kingzett sets forth the nature and causes of infectious diseases contain an admirably lucid and comprehensive *résumé* of a subject which is not easily dealt with save by skilled and able hands. The author's special investigations on the action of antiseptic agents are recorded with particular reference to the powers of the well-known Sanitas preparations; and in this connection the book under review contains an amount of interesting and most valuable information of use to all who are concerned in health processes. A new chapter on "Alimentation and Foods" is a distinctly good feature in the volume, and is calculated to add considerably to its importance by making it more complete than the former editions were as a manual of practical hygiene. The sections dealing with ventilation, water, sewage and its removal and treatment, are clear and well written; and the introductory chapter on chemical laws leaves nothing to be desired. In the handsome shape in which the publishers have produced the book it worthily ranks among the most important of the many recent treatises on sanitary science.

◆

Medical News and Pass Lists.

The Dental Hospital of London.

AN exhibition of pictures on behalf of the building fund of the Dental Hospital of London is now open at Prince's Hall, Piccadilly. It is held under Royal and distinguished patronage, and embraces a fine collection of paintings by well-known artists. The East Room is filled by a number of examples of Chappel's work, some of which are superb. Of the rest of the paintings it need only be remarked generally that they include many well-known paintings of first importance. The exhibition will be open from June 25th to July 2nd and one of its special features is an afternoon concert, at which many distinguished musicians and vocalists will appear. We can cordially recommend all lovers of art to pay a visit to this collection, especially as its object is to aid the extension of so deserving a charity as the London Dental Hospital. The honorary secretary is Mr. Knowsley Sibley.

West London Hospital.

A HIGHLY successful ball was held a few evenings since at Queen's Hall, Portland Place, on behalf of the West London Hospital. The visitors numbered 587, and the brilliancy of the scene was diversified by a party of the hospital nurses and by the scarlet uniforms of the band of the Scots Guards. Altogether, the affair proved one of the best dances of the season, and the Honorary Secretary, Mr. Percy Dunn, F.R.C.S., may be congratulated on its complete success.

London and Counties Medical Protection Society Dinner.

ON Tuesday, the 19th inst., the London and Counties Medical Protection Society gave their annual dinner at Frascati's Restaurant, the President, Mr. Jonathan Hutchinson, in the chair. After the usual loyal and patriotic toasts had been duly honoured, the chairman congratulated the society on its success during the past year.

(a) "Healthy Hospitals." By Sir Douglas Galton, K.C.B. Oxford: Published at the Clarendon Press.

(a) "Nature's Hygiene." By C. T. Kingzett, F.I.C., F.C.S. London: Bailliere, Tindall, and Cox. Fourth Edition, 1891.

He alluded to an alteration in the laws, by which members were liable to an emergency call of ten shillings in order to meet any unexpected strain on their resources. The finances of the body were sound, although the prosecution of the Indian oculists had somewhat taxed their elasticity. During the evening many guests, including several ladies, Professor Romano, of the Guildhall School of Music, entertained the company with a good musical programme. The usual speeches and toasts were given, and the affair proved thoroughly enjoyable. Dr. Woods, the energetic secretary, may be congratulated on the result, which fitly winds up a successful year. The number of members now on the list exceeds 1,000.

Ramsey, Isle of Man.

That health resorts are subject to the same vicissitudes as individuals is frequently made manifest. Recently, interested parties have spread evil reports concerning the healthiness at Ramsey and the medical profession resident thereat have come forward to the help of the Town Commissioners to verify the fact that it was never in a more healthy condition, and that no case of infectious disease has occurred during the past eight months. It appears that formerly a large portion of the sewage of the south side of the town was drained into the harbour. Now, however, by the extension of the sewage system designed by Mr. Mansergh, C.E., nearly the whole of that sewage is intercepted, and prevented from going into the harbour. The sewerage extension works have been in progress since February, 1893, and will be completed in a few days, when the sewerage system of Ramsey will be second to none in the United Kingdom.

Henley Regatta.

The approach of Henley Regatta, which will take place from the 4th to the 6th July, reminds one of the coming end of the London season, and we have been asked to mention that those members of the profession who purpose going up the Thames, will find select and comfortable accommodation in the "Clubland Enclosure." This site has a good river frontage, and is provided with an ample marquee and smaller tents, with a band, and every facility for eatering.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 31, Bombay 32, Madras 29, Paris 21, Brussels 16, Amsterdam 16, Rotterdam 15, The Hague 14, Copenhagen 17, Stockholm 16, Christiania 16, St. Petersburg 25, Moscow 30, Berlin 17, Hamburg 17, Dresden 17, Breslau 25, Munich 24, Vienna 22, Prague 37, Buda-Pesth 25, Trieste 28, Rome 18, Turin 19, Venice 22, Cairo 55, Alexandria 40, New York 19, Brooklyn 17, Philadelphia 16, New Orleans 32.

University College, Liverpool.

Our Liverpool correspondent informs us that Mr. George Holt, of that town, has given five thousand pounds to University College, Liverpool, which is to be invested to maintain the pathological and bacteriological laboratories of the University. The Council of the University College, Liverpool, have made two important professional appointments—Professor Paterson, M.D., Edinburgh, and Professor R. W. Boyce, M.D., London—the former to the chair of Anatomy, founded by Lord Derby, and the latter to that of Pathology, endowed by Mr. George Holt. Professor Paterson has for some years occupied a similar chair at Dundee University College. Professor Boyce has for several years been Assistant Professor of Pathology at University College, London.

University of Oxford.

At a Convocation holden on June 21st, the following degrees were conferred:—Doctors in Medicine: Ernest H. Cartwright, Exeter; Lewis E. Parkhurst, Jesus; Herbert P. Hawkins, Pembroke. Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Benedict.—There is such a society, but its benefits are restricted to practitioners resident within twenty miles of Charing Cross. This particular society is, moreover, on a charitable basis. For most practitioners a policy of assurance affords the only means of providing against the contingencies named. Such policies, however, possess, after a few years, a tangible cash value (surrender value) which does not apply to the other.

M. PASTEUR ON RABIES.

M. Pasteur addressed the following reply to a lady who recently wrote to him for information respecting the symptoms of rabies:—

M. Pasteur has had pleasure in receiving your letter of the 31st of May. The bite of a dog is only dangerous when the dog has got rabies. If there is any doubt in respect to this, the manner in which it may be found out is the following. Put the dog that has bitten where it can do no further harm. Have it examined by a vet, and if it has the rabies its characteristic symptoms will not be long of being observed, and the animal will certainly die in eight days. If at the end of that time no symptom of rabies has been observed the bite cannot cause hydrophobia, and there is no reason that the animal should be destroyed

Dr. Arthur J. Wallace (Liverpool).—Your "Note on the History of a case of Chronic Inversion of the Uterus" is marked for early insertion.

Mr. J. M. S.—Your bookseller has not misled you; we have inquired of the publisher, and find the number you require to complete your set is quite out of print.

Dr. H. P. G.—The case is hypothetical. If you will supply us with full data we shall be happy to give an opinion thereon.

SHORTHAND IN MEDICINE.

We have been asked by Dr. Gowers to state that, in order to promote the use of shorthand by medical students and practitioners, by enabling them to increase their knowledge at the same time of the art and of their profession, a small sheet of clinical teaching in lithographed phonetic shorthand has been printed. It can be obtained, price 6d., post free, from Messrs. Sir I. Pitman and Sons, 1 Amen Corner, and is also sold by Mr. H. K. Lewis, of Gower Street.
